Foreword

The Central Government introduced a variety of policies and programs throughout the Five Year Plans to address the issue of drinking water. The first ever national water supply and sanitation program was introduced during 1951-56 as part of the Government health plan. The states gradually built up the Public Health Engineering Department (PHED) to tackle the problem of rural water supply and sanitation. In spite of this, it was found during the mid-1960s that majority of the schemes were being implemented in the easily accessible villages, neglecting remote villages with severe water scarcity. The Central Government requested the States to identify these problem villages and make special plan for them.

The first major push to rural water supply came with the Accelerated Rural Water Supply Programme (ARWSP) in the 1970s, which gave full grant to the State Governments for implementing water supply schemes in problem villages. By March 1981, the coverage of rural water supply was 30.8 per cent. Following the International Drinking Water Supply & Sanitation Decade (IDWSSD-1981-91), the second major push came with the launching of the National Drinking Water Mission (NDWM) that was later renamed as Rajiv Gandhi National Drinking Water Mission (RGNDWM). The Mission issued comprehensive guidelines for ARWSP (1986), helped formulate National Water Policies (1987 and 2002) and introduced the sector Reform Project (SRP) in 1999. The focus of the RGNDWM was to adopt a community based demand-driven approach instead of the hitherto government forced supply driven approach. In doing so, the projects under RGNDWM are basically oriented towards community participation with a part (minimum of 10%) of the capital cost required to be borne by the community themselves. The balance amount is contributed by the Central Government.

In order to accomplish the envisaged objective of any scheme/programme, it is essential to put in place a mechanism for regular monitoring and evaluation at recurrently close intervals. In keeping with the importance of the mission, a comprehensive evaluation study of RGNDWM was initiated by the Programme Evaluation Organization.

Among the 5 selected states, Himachal Pradesh stands out as unique in the sense that almost all women (96%) have asserted their increased participation in the community activities. As regards the program's impact on children, an overwhelming majority of women(89%) have reported that on account of improved water supply(easier access and adequate availability), children have now more time set apart for study and play, earlier devoted to helping them collect water. Overall, an overwhelming majority (96%) of the households have reported increased usage of water.

Government accords great importance to the objective of measuring outcomes so as to ensure that policies serve the purposes for which they were adopted. The role of the Programme Evaluation Organisation(PEO) is crucial in undertaking systematic studies to assess the degree of the effectiveness of programmes, primarily as an input to future policy. Evidence of sub-optimality suggests the need to draw lessons from observed weaknesses and redesign programmes accordingly. The Planning Commission proposes to strengthen this aspect of its activity in the years ahead.

(Montek Singh Ahluwalia)

PREFACE

The national goal of achieving universal access of the mammoth rural population to adequate potable drinking water at a convenient location at all times is a daunting task. The major challenge is the availability of drinking water, both in term of adequacy and quality on a sustainable basis. The Government has undertaken various programs since independence to provide safe drinking water to the rural masses. Taking into account the magnitude of the possibilities, the Central Government, in an effort to deal the issues in a mission mode, launched in 1986, National Drinking Water Mission, later renamed as Rajiv Gandhi National Drinking Water Mission (RGNDWM) in 1991.

The Government is committed to ensure that the village communities have access to safe and reliable water supply and it is evident from the fact that since the beginning of the planned era of development, huge investment of about Rs 72,600 crore has been made in the rural water supply sector under both State and Central Plans up to 2009.

In view of the importance of the Mission, the Programme Evaluation Organisation (PEO) of Planning Commission was entrusted to conduct an evaluation study on RGNDWM to assess the processes involved during implementation and the overall impact of the mission of the rural population.

Government accords great importance to the objective of measuring outcomes so as to ensure that policies are producing the desired results. The PEO provides a key input into this process by undertaking systematic evaluation studies, primarily to draw lessons that can be applied to ensure effectiveness of the future policy and programs.

The present evaluation study covered 240 habitations spread over 10 sample districts across five geographically representative study states and looked at the extent of coverage, access and the overall impact of the Mission on the rural habitations, especially on women.

The supply of safe drinking water and provision of sanitation are the two most important contributing factors for improving the health of the people in the country.

The main findings of this evaluation study on the basis of drawn samples are:

- ❖ 93% of the rural population at present has access to safe drinking water in the covered states.
- ❖ 66% of the households having access to safe drinking water source are getting round the year supply of drinking water.
- ❖ It is encouraging to note that an overwhelming majority of the households (93%) have reported their satisfaction with the water quality.

- ❖ 70% of the handpumps and 91% of the tapped water supply sources in the sample villages were functional as reported by the respondents during the field investigation.
- ❖ 87% of the households have reported to be paying the water charges on a regular basis and 95% of the households have expressed their satisfaction with regard to the water charges paid by them vis-à-vis the quantity/quality received by them in the covered states.
- ❖ Most of the households mentioned about non-existence of Village Water and Sanitation Committee (VWSC) in their area.
- ❖ 74% of the households have reported that the programme has a positive impact in terms of environmental sanitation.
- ❖ 75% respondents have conveyed that the workload on women has reduced drastically due to the implementation of the programme.
- ❖ 89% of the women have also reported that the children are getting more time for studying instead of helping them in collecting water from the natural sources.

The study also brought some important suggestions for better functioning of the programme. These are:

- ❖ The Village Water and Sanitation Committees (VWSCs) are required to be revitalized and made functional.
- ❖ The PRI members should be provided adequate training for their active involvement in the implementation of the Programme.
- ❖ Awareness programmes with regard to the Mission should be organised on regular basis in the remote villages for its success.

The study received constant support and encouragement from Honourable Deputy Chairman, Planning Commission and Member-Secretary, Planning Commission. The study was outsourced to M/s. AMS Consulting Pvt. Ltd. Lucknow. I extend my thanks to the Director and other associates of the Institute for conducting the field study and preparing the study report. The study was designed and conducted under the direction of Dr. R.C.Dey, Director, PEO with the assistance of Ms. Krishna Veni Motha, the then Consultant, Shri L.N.Meena and Shri Vipin Kumar, Economic Officers of PEO. The report is finalized and brought to the present shape under my supervision. The help and co-ordination received from all concerned for preparation of the report is gratefully acknowledged.

Executive Summary

1. Background

Meeting the drinking water needs of 700 million rural population settled in about 1.42 million habitations spread over 15 diverse ecological regions can be a daunting task. The major challenge in the Rural Water Supply sector is the availability of drinking water, both in term of adequacy and quality on a sustainable basis. Despite collective effort of the State and Central Governments and huge investment of about Rs 72,600 crore in the rural water supply sector, the national goal of providing adequate potable drinking water to the rural community at a convenient location at all times is yet to be achieved.

2. Study Objectives

1. Assess the extent of coverage and access to improved services in the rural areas;
2. Assess the institutional arrangements placed by the State Governments for implementation and performance of the mission;
3. Evaluate the overall impact of the mission on the rural habitations, especially on women in terms of access to improved water services and awareness;
4. Identify the measures adopted for ensuring the sustainability of the surface water and ground water sources and constraints there-upon;
5. Assess the role of the stakeholders at various levels in creating awareness about water and sanitation among the beneficiaries; and
6. Document the major achievements in rural water services under RGNDWM.

3. Sampling Plan

Sampling of the 5 study states and 10 districts was done by the Planning Commission. Two blocks in each sample district were selected based on the largest number of completed schemes. In each block, 3 Gram Panchayats and from each Gram Panchayat, 4 habitations were selected. For the purpose of impact assessment, 6 households were selected from each sample habitation giving adequate representation to the various socio-economic categories. Thus, a total of 1440 households were covered from 240 habitations in 60 Gram Panchayats spread over 20 blocks of the 10 sample districts across 5 study states. The study schedules for various stakeholders containing a judicious mix of questions seeking quantitative and qualitative information were developed and supplied by the Planning Commission.

4. Major Findings

Status of Fully Covered Habitations : As per the official records, between the period 2003 and 2009, there has been a significant increase in the proportion of fully covered (FC) habitations in all the 5 study states (14 to 62 percentage points). Presently, the fully covered habitations in these states are found to be in the range of 75% to 95%.

Access to Safe Drinking Water

There has been a tremendous improvement in the rural populations' access to safe drinking water sources between the pre-2003 and the present period across all the 5 states. Overall, 5 states combined, over nine-tenth (93%) of the rural population at present has access to safe drinking water sources; the improvement of 32 percentage points is a reflection of the commendable progress made under the Mission. With the advent of the Mission, the situation in the most affected areas has improved to a point where the proportions of the households in least and most affected areas having access to safe drinking water are quite comparable (92% and 95%, respectively).

Safe and Round-the-year Availability : Overall, around two-third (66%) of the households having access to safe drinking water sources are getting round-the-year supply of drinking water. Among the 5 states, Assam stands out as the best performing State with nearly four-fifth (76%) of the households receiving round-the-year supply of water from safe sources. On the other hand, West Bengal is found to be the worst performing, where two-fifth (42%) of the households have reported that they are deprived of this facility.

Safe, Round-the-Year and Sufficiency : Overall, only three-fifth (63%) of the households has reported to be receiving sufficient quantity of water from safe sources on round-the-year basis. Among the 5 states, Assam stands out as the best performing State where this was reported by three-fourth (76%) of the households. On the other hand, Karnataka was found to be the worst performing State (46%). It has been found that although the proportion of households having access to safe water is quite high (85% to 100%), the proportion reporting safe, round-the-year and sufficient water supply is much smaller (54% to 76%).

Moving towards Tapped Water Supply : Compared to their status prior to 2003 and present (2009), the proportion of households having access to tap water has improved quite significantly in all the 5 states (from 24% to 71%), with a significant decline in the proportion of households dependent on hand-pump/tube-bore wells.

Water Quality

Satisfaction with the Water Quality : It is encouraging to note that overall, an overwhelming majority of the households (93%) have reported to be satisfied with the water quality. Among the 5 states, water quality is a major issue only in the State of Rajasthan, as reported by half the households (50%) surveyed in the State. There is not much difference between the 'least affected' and 'most affected' districts in terms of water quality as perceived by the households.

Water Testing : It is disheartening to note that out of the 63 sample Gram Panchayats, only 18 have reported about being provided with the field-testing kit. Surprisingly, none of the 14 sample Gram Panchayats of West Bengal and only 1 Gram Panchayat in Assam has reported affirmatively in this regard. Ironically, the proportion of GPs provided with the field testing

kits is much smaller for the ‘most affected’ districts as compared to the ‘least affected’ ones (23% vs 33%). Further, four-fifth (79%) of the sample habitations have reported in negative about the testing of water sources in their villages.

Trainings on Water Quality Monitoring and Surveillance : The *Pradhans* of only 23 out of the 63 sample GPs affirmed about the provision of training to grassroot workers. Among the 5 states, Karnataka stands out with all the 12 sample GPs reporting the provision of training to grassroot workers. Gender-wise, it emerged that in a large majority of the Gram Panchayats (50 out of 63), no woman has received any training.

Operation & Maintenance

Functional Water Sources : Over two-third (70%) of the hand-pumps and overwhelming majority (91%) of the tapped water supply sources were functional as reported by the respondents of the habitations survey. The major reasons for the defunct hand-pumps were cited as ground water depletion and lack of proper maintenance.

Responsibility of O&M : Overall, only a small proportion (5%) of the households was of the view that O&M should be the responsibility of the community. Among the 5 states, Himachal Pradesh stands out with the proportion of such households being the highest (12%). *When probed about the existence of any committee in their village/habitation that is responsible for maintenance of water sources, almost all the households (99%) responded in negative.* The proportion of households willing to pay for the operation & maintenance of the water supply system was found to be very small (8%). While prevailing poverty was cited as one of the major reasons, a majority of the community members considered O&M as the responsibility of the GPs.

Role of GPs in O&M of Water Supply System : Over half of the Gram Panchayats have expressed their inability to take the responsibility of O&M. In a large majority of the Gram Panchayats (50 out of 63), formal handing over of O&M of the assets created under the Mission has not been done.

Water Tariff

Close to nine-tenth (87%) of these households have reported to be paying water charges on a regular basis. Almost all (95%) the households have expressed satisfaction with regard to the water charges paid by them vis-a-vis the quantity/quality of water supply received by them. The average amount of monthly water charges per household is found to be lowest (Rs. 12.70/- in Himachal Pradesh and highest (Rs. 53.80/-) in Assam, with no variations in the water charges among the households belonging to the different social categories. Further, an overwhelming majority (88%) of the households having tap connections had paid installation charges. This was lowest (Rs. 526.60/- per household) in Himachal Pradesh and highest (Rs. 1840.00/- per month per household) in West Bengal.

It may be highlighted that the user charges for Public Stand Post (PSP) were collected only in the State of Karnataka, as reported by the village Pradhans of the 12 sample Gram Panchayats. According to them, the average monthly amount of water charges per household was Rs. 10/- for all sections of the society.

Community Participation/Existence of VWSC

It is disheartening to note that less than 1% of the households mentioned about the existence of village water and sanitation committee (VWSC) in their areas. When discussed with the *Pradhans*, it emerged that VWSCs were existing in only one-fifth (13 out of 63) of the sample Gram Panchayats. Among the 5 states, Karnataka stands out where the presence of VWSC was reported by half the sample Gram Panchayats. While VWSC meetings were reportedly conducted only in 9 out of the 13 GPs, participation of women and scheduled caste community members in the VWSC meetings was reported in only 7 out of the 13 GPs. Further, in only 6 out of the 13 GPs, all VWSC members have reportedly received training.

IEC on Hygiene & Sanitation

At the household level, barring Himachal Pradesh, the situation in the other 4 states is pathetic, with their proportion responding in affirmation about any IEC campaign ranging between 0% and 8%. In the near absence of IEC activities, it is no surprise that open defecation is so widely prevalent in most (80%) of the sample habitations.

Program Benefits/Impact on Rural Population

Increased Availability of Water/Reduced Breakdowns: Increased availability and consequently, increased water usage by the rural households have been found to be the biggest program benefits. Overall, an overwhelming majority (96%) of the households have reported increased usage of water. Further, four-fifth (80%) of habitations mentioned that the number of water sources in functional condition has significantly increased in the last few years, while 57% of them mentioned about noticeable decrease in the frequency of the supply system breakdowns.

Improved Environmental Sanitation & Reduction in Water Borne Diseases: Overall, three-fourth (74%) of the household survey respondents felt that the Program has had a positive impact in terms of environmental sanitation. This was most prominent in the State of Himachal Pradesh (95%). This was corroborated by three-fourth (75%) of the habitation survey respondents.

Improvement in Women's Conditions : Overall, a significant three-fourth (75%) of the respondents have reported in affirmation about reduction in their workload. Due to reduced workload, there has been a significant reduction in fatigue experienced by women. Consequently, women have now more time to engage themselves in various community activities. Further, an overwhelming majority of women (89%) have reported that children have now more time for studying and playing, instead of helping them collect water.

Utilization of Time Saved : People are now able to spend time in more productive activities instead of spending excessive time in collecting water, with a significant amount of ‘opportunity cost’ associated with it. People are now utilizing the time saved for income generating activities (agriculture, cattle rearing, etc.).

Sustainability

In order to calculate the *Sustainability Index*, a total of 29 parameters under 5 broad aspects, namely, *technology aspects, community and social aspects, financial aspects, water quality aspects* and *training aspects* were identified. For each of these 29 parameters, the responses from the households were quantified on a scale of 1 to 4 and State-wise averages were computed for each of them. Sustainability index of 76%-100% was considered highly satisfactory, 51%-75% considered as satisfactory, 26%-50% considered as poor and 0%-25% was considered as very poor.

Composite Sustainability Index : Overall (all states and aspects combined) sustainability index works out to 54%, which is only marginally above the range of ‘Poor’. While West Bengal and Rajasthan have performed poorly (49% & 46%, respectively), it was satisfactory for Himachal Pradesh, Assam and Karnataka (58%, 52% and 66%, respectively).

Technological Aspects : The overall (all 5 states combined) sustainability index in respect of the technology issues is found to be 71%, which is satisfactory. While it is highly satisfactory for Karnataka (78%), it is satisfactory in case of the other 4 states (65% to 74%).

Community & Social Aspects : Overall (all 5 states combined) sustainability index is found to be 63%, which is satisfactory. Performance of all the 5 states is found to be satisfactory, with Rajasthan scoring lowest (55%) and Karnataka scoring the highest (74%).

Financial Aspects : Findings on sustainability index with respect to financial aspects shows that overall situation is very poor (23%). State-wise, the performance of Rajasthan, West Bengal and Assam is found to be very poor (9%, 15% and 19%, respectively), while it was poor for Himachal Pradesh and Karnataka was found to be poor (34% and 37%, respectively).

Water Quality Aspects : In terms of water quality, the sustainability index of Karnataka and Himachal Pradesh is found to be highly satisfactory (94% and 93%, respectively), while the other 3 states have fared satisfactorily in this regard (69% to 71%). The overall (all 5 states combined) sustainability index is also found to be highly satisfactory (80%).

Training Aspects : The overall situation (all 5 states combined) presents a poor picture with a sustainability index of only 30%, implying that the provision of training to community members, especially the women has not been given adequate and much needed attention.

Evidently, the poor performance of the states with respect to ‘financial aspects’ and ‘training of community members’ has had an adverse impact on the overall composite sustainability index and it has barely managed to be in the ‘satisfactory range’ (54%). A comparison of

overall sustainability index with respect to each of the 5 broad aspects for ‘most affected’ and ‘least affected’ sample districts shows any noticeable variations only in the case of ‘water quality’ aspect (76% and 84%, respectively). As regards the other four broad aspects, the values of sustainability indices are quite comparable.

Installation of Rain Water Harvesting Structures : The study has shown that rain water harvesting structures have been installed only in less than two-fifth (36%) of the sample GPs. Surprisingly, none of the GPs in West Bengal and Assam have reported about installing such structures.

Recommendations

1. *In the light of the fact that in most cases, the Village Water and Sanitation Committees (VWSCs) are non-functional, the first step would therefore be to revitalize these committees and build the capacity of their members. Only then, the goals and objectives of the Mission can be realized.*
2. *In the light of the study revealing a near total absence of community involvement (what to talk of the involvement of women), it becomes crucial to engage specialist agencies for capacity building of VWSC members. Only then, the needs and aspirations of the rural poor can be fulfilled.*
3. *It would be worthwhile to take-up focused and sustained IEC campaigns to educate the communities on the various aspects and issues related to drinking water, sanitation and hygiene. This would also motivate the communities, especially the women for their active involvement in all aspects of the Mission, including its operation & maintenance. For the purpose, experienced professional agencies may be hired to develop appropriate and effective IEC tools.*
4. *There is an urgent need to organize relevant training programs for the village level PRI members so as to motivate them for their active involvement in all aspects of the Mission. For the purpose, professional training agencies may be hired.*
5. *The program managers may consider a separate and adequate budgetary provision, besides deputing a team of dedicated staff for ensuring timely repairs and preventive maintenance of the assets created under the project.*
6. *In view of less than two-fifth (36%) of the sample GPs having installed rainwater-harvesting structures, there is an urgent need for the renewed impetus in taking-up this important water conservation measure in a serious manner.*
7. *In order to ensure effectiveness and long-term sustainability of the rural water supply schemes under the Mission, it is imperative to design State-specific plans of action keeping in mind the needs and aspirations of the rural populations.*

* * * * *

1. Introduction

1.1 Background

In India, although the provision of rural water supply (RWS) is primarily the responsibility of the respective State Governments, the Central Government contributes a significant part of the program funds for this sector. Throughout the Five Year Plans, the Central Government introduced a variety of policies and programs to address the issue of drinking water. The first national water supply and sanitation program was introduced during 1951–56 as part of the Government’s health plan. The states gradually built up the Public Health Engineering Department (PHED) to tackle the problem of rural water supply and sanitation. In spite of this, it was found during the mid-1960s that majority of the schemes were being implemented in the easily accessible villages neglecting remote villages with severe water scarcity. The Central Government requested the states to identify these problem villages and make special plans for them.

The first major push to rural water supply came with the Accelerated Rural Water Supply Program (ARWSP) in the 1970s, which gave full grant to the State governments for implementing water supply schemes in problem villages. By March 1981, the coverage of rural water supply was 30.8 per cent. Following the International Drinking Water Supply & Sanitation Decade (IDWSSD) [1981-91], the second major push came by establishing the National Drinking Water Mission (NDWM), later renamed as the Rajiv Gandhi National Drinking Water Mission (RGNDWM). The Mission issued comprehensive guidelines for ARWSP (1986), helped formulate National Water Policies (1987 and 2002) and introduced the Sector Reform Project (SRP) in 1999.

With the introduction of the SRP, it became the world’s largest, Government sponsored demand based and participatory drinking water supply program, which was first implemented in 67 districts of 26 states in India on a pilot basis. Community participation was sought through 10 per cent contribution to the total installation cost and full responsibility for operation & maintenance. Significant investments were made in building community capacity, and in providing information, education and communication (IEC). While there remained much to be learnt from the infirmities of the SRP, it was scaled up in the form of Swajaldhara in December 2002 with the objective of covering the entire country by the end of the Tenth Five Year Plan.

The various drinking water supply programs & policies at a glance in chronological order is presented in the following table.

Drinking Water Supply Programs & Policies at a Glance

1949	The Environment Hygiene Committee (1949) recommends the provision of safe water supply to cover 90 per cent of India's population in a timeframe of 40 years.
1950	The Constitution of India confers ownership of all water resources to the government, specifying it as a state subject, giving citizens the right to potable water.
1969	National Rural Drinking Water Supply program launched with technical support from UNICEF and Rs.254.90 crore is spent during this phase, with 1.2 million bore wells being dug and 17,000 piped water supply schemes being provided.
1972-73	Introduction of the Accelerated Rural Water Supply Program (ARWSP) by the Government of India to assist states and union territories to accelerate the pace of coverage of drinking water supply.
1981	India as a party to the International Drinking Water Supply and Sanitation Decade (1981-1990) declaration sets up a national level Apex Committee to define policies to achieve the goal of providing safe water to all villages.
1986	The National Drinking Water Mission (NDWM) is formed.
1987	Drafting of the first National Water Policy by the Ministry of Water Resources.
1991	NDWM is renamed the Rajiv Gandhi National Drinking Water Mission (RGNDWM).
1994	The 73rd Constitutional Amendment assigns Panchayati Raj Institutions (PRIs) the responsibility of providing drinking water.
1999	<p>For ensuring sustainability of the systems, steps are initiated to institutionalize community participation in the implementation of rural drinking water supply schemes through sector reform. Sector reform ushers in a paradigm shift from the 'Government-oriented supply-driven approach' to the 'People-oriented demand-responsive approach'. The role of the government is envisaged to change from that of service provider to facilitator. Under reform, 90 per cent of the infrastructure is funded by the government, with the community contributing 10 per cent of the remaining infrastructure cost and 100 per cent of operation and maintenance costs. Sector reforms projects were introduced in 67 districts across the country on pilot basis.</p> <p>Total Sanitation Campaign (TSC) as a part of reform principles initiated in 1999 to ensure sanitation facilities in rural areas with broader goal to eradicate the practice of open defecation. As part of the program, a nominal subsidy in the form of incentive is given to rural poor households for construction of toilets. TSC gives strong emphasis on Information, Education and Communication, Capacity Building and Hygiene Education for effective behavior change with involvement of PRIs, CBOs, and NGOs</p>
2002	<p>Nationwide scaling up of sector reform in the form of Swajaldhara.</p> <p>The National Water Policy is revised, according priority to serving villages that did not have adequate sources of safe water and to improve the level of service for villages classified as only partially covered.</p> <p>India commits to the Millennium Development Goals to halve by 2015, from 1990 levels, the proportion of people without sustainable access to safe drinking water and basic sanitation.</p>

2004	All drinking water programs are brought under the umbrella of the RGNDWM.
2005	The Government of India launches the Bharat Nirman Program for overall development of rural areas by strengthening housing, roads, electricity, telephone, irrigation and drinking water infrastructure. The target is to provide drinking water to 55,069 uncovered habitations; those affected by poor water quality and slipped back habitations based on 2003 survey, within five years.
2007	<p>Pattern of funding under the Swajaldhara Scheme changes from the previous 90:10 central-community share to 50:50 centre-state share. Community contribution is now optional.</p> <p>The approach paper for the 11th Five Year Plan calls for a comprehensive approach which encompasses individual health care, public health, sanitation, clean drinking water, access to food and knowledge about hygiene and feeding practice. It also states the need to upscale more schemes related to community management of water reducing the maintenance burden and responsibility of the state. It is envisaged to provide clean drinking water for all by 2009 and ensure that there are no slip-backs by the end of the 11th Plan.</p>

1.2 Rajiv Gandhi National Drinking Water Mission

The focus of the Rajiv Gandhi National Drinking Water Mission (RGNDWM) was to adopt a community-based demand-driven approach instead of the hitherto government forced supply driven approach. In doing so, the projects under RGNDWM are basically community participation oriented in nature – with a part (minimum of 10% of the proposal) of the capital cost required to be borne by the community themselves. The balance amount is contributed by the Government of India.

As per the guidelines, the implementing agencies for the program may be decided by the respective State Governments. The implementation should be entrusted to one single Department in the State, with a view to better implementation, monitoring of the progress and the like. If the program has to be implemented through more than one Department, one of the Departments should be designated as the Nodal Department for co-coordinating the Rural Water Supply Programs and sending consolidated progress reports to the Central Government. The Panchayati Raj Institutions (PRIs) are also supposed to be involved in the implementation of schemes – particularly in the selection of the location of stand-posts, spot sources, operation and maintenance, fixing of water tariff, etc.

The Population Census data indicate that in 2001, about 78 percent of the rural population had access to a safe source of drinking water, up from 56 percent in 1991. The Rajiv Gandhi National Drinking Water Mission (RGNDWM) had set a target of extending access to safe drinking water for 100 percent of the rural population by 2007. Although this target has not

been fully achieved, the expansion of coverage attained during the 1990s, as reflected in the Census data, shows the objective of 100 percent safe water access should not be difficult to achieve in the next five years or so. Indeed, the Eleventh Five Year Plan (2007-08 to 2011-12) foresees the provision of safe drinking water to all rural habitations.

1.3 Critical Issues

Availability of and access to safe potable water have been an area of deep concern mainly due to the multifarious challenges these pose in managing and ensuring a sustainable supply for the fast growing population. Rural India has more than 700 million people residing in about 1.42 million habitations spread over 15 diverse ecological regions. Meeting the drinking water needs of such a large population can be a daunting task. The non-uniformity in level of awareness, socio-economic development, education, poverty, practices & rituals and water availability add to the complexity of the task. In many parts of rural India, a crisis of drinking water has assumed such proportions that it has led to large scale out-migration, 'water riots', inter-state disputes over water sharing and conflict between rural and urban consumers.

The major issues in the Rural Water Supply sector are lack of sustainability of drinking water sources and systems. As a consequence, availability of drinking water, both in term of adequacy and quality on a sustainable basis has become a major challenge. Water quality has become a major issue as ground water table goes down further. The levels of contaminants, such as, fluoride (66 million people across 17 States are estimated to be at risk), arsenic (nearly 13.8 million people in 75 blocks are reported at risk), varying iron levels, presence of nitrates and heavy metals, bacteriological contamination and salinity and man-made chemical pollutants, such as, pesticides and insecticides are high and still rising. The health burden of poor water quality is enormous. It is estimated that around 37.7 million Indians are affected by waterborne diseases annually, 1.5 million children are estimated to die of diarrhea alone and 73 million working days are lost due to waterborne disease each year.

According to official statistics, the proportion of fully covered habitations reached 97 percent by April 2006 (Economic Survey, Government of India, 2006-07), up from about 75 percent in 1997. This, however, does not take into account the slippages that have taken place— habitations once fully covered have later slipped into 'partially covered' or 'not covered' status for various reasons (water sources going dry or getting quality affected; systems working below capacity due to poor operation and maintenance; increase in population in the habitations resulting in lower per capita availability; and so on). Indeed,

the preliminary results of the Habitation Survey (2003) provide indications of significant slippage and give the impression that coverage has not been increasing much.

Despite collective effort of the State and Central Governments and huge investment of about Rs 72,600 crore in the rural water supply sector, under both State and Central Plans up to 2009 since the beginning of the planned era of development, the national goal of providing adequate potable drinking water to the rural community at a convenient location at all times is yet to be achieved. In other words, reliable, sustainable and affordable service is still lagging.

It may also be highlighted that traditionally, rural water supply in India has followed a supply-driven approach with access to safe water being considered a social good. Supply-driven programs incur large institutional costs, substantially raising the cost of service provision. Consequently, it has resulted as a hindrance to the development of more efficient and lower cost options for service delivery and also denying opportunity to the users to exercise their options as consumers to demand better service delivery. The demand-responsive approach on the other hand, is based on the principles of community participation and decentralization of powers for implementing and operating drinking water supply schemes with the government playing the role of a facilitator. Demand-driven programs are found to have relatively low institutional cost and other advantages, including better O&M cost recovery.

1.4 Objectives of the Study

In order to accomplish the envisaged objectives of any scheme/program, it is essential to institutionalize a mechanism for regular monitoring and evaluation from time-to-time. Regular monitoring and in-depth evaluation provides valuable insights on how well we have done in the past and to report to stakeholders the return on their investment and to underpin political support for continued investment. Besides, the lessons learnt can be applied in improving the program by incorporating vital information into planning, resource allocation and prioritizing future programs & activities.

In the light of the above and keeping in view the importance of the mission, a comprehensive 'Evaluation Study of the Rajiv Gandhi National Drinking Water Mission (RGNDWM)' was aptly initiated by PEO, Planning Commission (GoI). AMS Consulting (P) Limited was commissioned for this study.

The reference period of the study was 2003-04 to 2006-07. The specific objectives of the study were to —

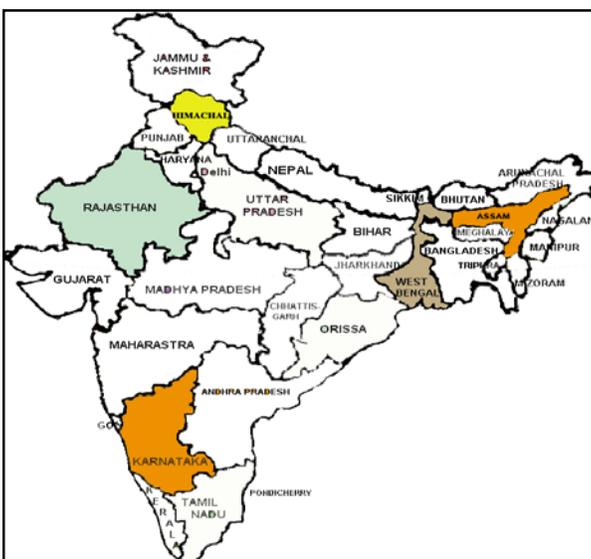

1. Assess the extent of coverage and access to improved services in the rural areas;
2. Assess the institutional arrangements placed by the State Governments for implementation and performance of the mission;
3. Evaluate the overall impact of the mission on the rural habitations, especially on women in terms of access to improved water services and awareness;
4. Identify the measures adopted for ensuring the sustainability of the surface water and ground water sources and constraints there-upon;
5. Assess the role of the stakeholders at various levels in creating awareness about water and sanitation among the beneficiaries; and
6. Document the major achievements in view of the interventions in rural water services under RGNDWM.

2. Methodology

2.1 Sampling Plan

Sampling of States & Districts

Sampling of the 5 study states and 10 districts was done by the Planning Commission. As mentioned in the Terms of Reference, one State each was selected from the five geographical zones of the country. Additionally, it was endeavored to ensure that the sample included due representation of the DDP areas, quality affected and hilly areas. The detailed State-wise sample for the study is presented hereunder.

S. No.	Zone	State	Selection Criteria
1	East	West Bengal	Plain Area
2	West	Rajasthan	Quality Affected
3	North	Himachal Pradesh	Hilly Area
4	South	Karnataka	Desert Development Program
5	North-East	Assam	North-East Region

Within each of the five states, a total of two districts were selected — with one district having the highest number of quality affected habitations and the second district with the least or no quality affected habitations. The details of the sample districts are presented hereunder —

Sl.	State	Sl.	District	Selection Criteria
1	West Bengal	1.	Bankura	Quality Affected
		2.	Howrah	Least Affected
2	Rajasthan	3.	Barmer	Quality Affected
		4.	Dholpur	Least Affected
3	Himachal Pradesh	5.	Bilaspur	Quality Affected
		6.	Kullu	Least Affected
4	Karnataka	7.	Kolar	Quality Affected
		8.	Shimoga	Least Affected
5	Assam	9.	Nagoan	Quality Affected
		10.	Guwahati	Least Affected

Sampling of Blocks

Two blocks in each of the two sample districts were selected. For the purpose, the AMS Consultants visited the office of the concerned implementing Agency of the sample districts and collected the detailed list of the drinking water supply schemes under Rajiv Gandhi National Drinking Water Mission (RGNDWM), which were completed during the reference period of the past 4 years (2003-04 to 2006-07).

In the next step, the completed schemes were arranged block-wise and subsequently, 2 blocks having the largest number of completed schemes were selected. Due care was taken to ensure that the 2 sample blocks were representative with regard to the diverse geographical conditions of the district and quality affected areas therein.

Sampling of Gram Panchayats & Habitations

After having selected the sample blocks, drinking water schemes were arranged Gram Panchayat-wise and subsequently, 3 Gram Panchayats having the largest number of completed schemes were selected. Similar to the sampling of blocks, care was taken to ensure that the 3 sample Gram Panchayats were representative with regard to the diverse geographical conditions of the sample block and quality affected areas therein. Then, from each of the sample Gram Panchayat, 4 habitations were selected. As per the ToR, one habitation each was to be selected from among the (a) Fully Covered, (b) Partially Covered, (c) Not Covered, and (d) Quality affected habitations.

It may be mentioned that only those habitations were selected where the drinking water supply schemes had been completed and drinking water was being supplied to the people. Further, sampling of Gram Panchayats and habitations was finalized after discussions and consultations with the concerned officials of the sample blocks.

Sampling of Households

For the purpose of impact assessment, 6 households were selected from each of the 48 habitations using the stratified purposive sampling method – giving adequate representation to the various socio-economic categories. Accordingly, four households from general category, one household from SC category and one household from ST Category were selected. In case of any shortfall in the required number of sample households in any stratum/category, the same was compensated from the remaining strata/ categories. Thus, a total of 1440 households were selected from 240 habitations in 60 Gram Panchayats spread over 20 blocks of the 10 sample districts across 5 study states.

From each of the households selected for the study, in-depth interviews (IDIs) were conducted with the female member of the household, since in the rural community, it is usually the women who are the mainly responsible to make arrangements for meeting the daily requirement of drinking water in the households. In case a woman member was not available at the time of interview, IDI was then conducted with the head of the household.

2.2 Information Gathering

Quantitative methods are enormously useful in impact assessment of development projects. Nonetheless, they have some important limitations in the sense that they fail to provide an adequate understanding of the mechanism instigating a series of events that ultimately result in the observed impact of the program. They fail to provide an answer to why and how the program has or has not been able to achieve its desired goals and objectives, thus limiting the scope for any corrective measures.

Such limitations can be overcome by incorporating qualitative approaches that would supplement, improve and complement the quantitative data. Qualitative methods provide an in-depth understanding of the needs, behaviors, aspirations and perceptions of the community for whom the development programs are intended, besides assessing the implementers' perspectives, that is, their limitations, problems and bottlenecks in program implementation. Accordingly, the study schedules for various stakeholders developed and supplied by the Planning Commission contained a judicious mix of questions seeking quantitative and qualitative information.

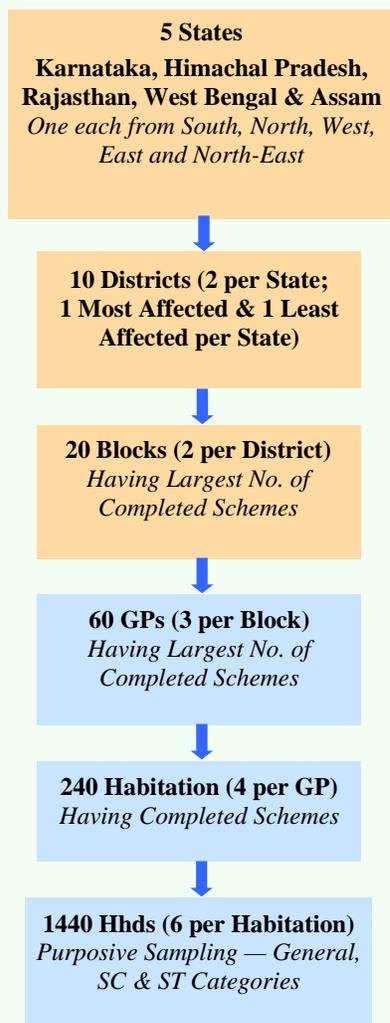

Besides information gathering using the aforementioned schedules, efforts were also made to conduct physical observation/verification during the transect walk through the sample Gram Panchayats/habitations. This helped us in understanding the various features within the selected villages, such as, the status of drinking water points vis-à-vis the standard of cleanliness/hygiene around these points, drainage facilities, etc.

Further, we focused our attention on areas of our concern by interacting directly with the members of the community (including those accompanying us, as well as those who we met during the transect walk). In doing so, our focus was on collecting vital information regarding various habitations within the village, the residents and their specific concerns pertaining to the availability of safe drinking water and more importantly, on the aspect of quality.

A schematic diagram of the study design comprising of the study sample and the key issues covered is presented ahead.

- Reliability
- Quality
- Participation
- Tariff
- Impact

Reference Period : 2003-04 to 2006-07

2.3 Training of Research Team Members

During the 2-day in-house classroom-training program, the research team members were rigorously trained on the implementation process and various other aspects of the Rajiv Gandhi National Drinking Water Mission (RGNDWM). Further, they were also trained on the technique of conducting in-depth interviews (IDIs) and focus group discussions (FGDs), besides orienting them on the sample study sites and the different stakeholders to be

interviewed. On the third day, the research team members were taken for field-testing of the study instruments. This was followed by a question-answer session that allowed them to clear doubts, if any, in their minds with regard to the study instruments or otherwise. The entire training exercise (including the field visit) was conducted under the guidance of the Planning Commission officials

2.4 Scheme of Data Analysis

While quantitative data was analyzed using standard statistical software, qualitative information gathered through in-depth interviews of implementers (State, district & block-level) and focus group discussions with the community was analyzed in a systematic and methodological manner, scrutinizing the textual information for its primary as well as latent content. The following procedure was adopted for the content analysis of the qualitative data

Free Listing : The responses to a particular question were listed to obtain the range of responses for all open-ended questions. The responses that were considered irrelevant under a specific question were moved under the appropriate question. During this process, the important statements or quotable quotes with their reference were extracted for use in the report as reference material.

Coding : In the final screening, for every open-ended question, responses were coded according to the domains. Some responses could be placed under more than one domain as a range of views was stated in a single sentence. After careful scrutiny, the responses found to be completely irrelevant were discarded.

Summarizing : Similar information sought from different stakeholders was triangulated to arrive at a conclusion with greater degree of accuracy, as also from the viewpoint of reliability and validity. The results were then summarized for each of the issues.

2.5 Computation of Sustainability Index

One of the prime objectives of the study was to assess the sustainability of water sources in the habitations. In order to calculate the *Sustainability Index*, a total of 29 parameters under 5 broad aspects, namely, *technology aspects*, *community and social aspects*, *financial aspects*, *water quality aspects* and *training aspects* were identified as detailed in the following table.

Technology Aspect

1. Functionality of Source
2. No. of functional points increased
3. Year round functionality of source
4. Break down frequency
5. Time taken for repairs
6. Availability of equipment/space
7. Technical skills of community

Community & Social Aspect

8. Ownership of water sources
9. Choice of technology
10. Access to all groups
11. Usage of sources
12. O&M measures taken
13. Community willingness to take O&M
14. Care of sources by women
15. Satisfaction with water services

Financial Aspect

16. Community contribution
17. Availability of funds
18. Entity setting-up water tariff charges
19. Affordability of water charges
20. Whether community consulted in tariff-setting
21. Flexibility in user payment
22. Provision of subsidized tariff for poor (SC/ST)

Water Quality Aspect

23. Acceptability of quality
24. No. of sources with acceptable quality
25. Access to safe water
26. Source reliability

Training Aspect

27. Category of personnel trained
28. Gender-wise training
29. Preference for women in training of hand-pumps repair

For each of the aforementioned 29 parameters, the responses from the households were quantified on a scale of 1 to 4 and State-wise averages were computed for each of them. This allowed us to identify the critical sustainability parameters that were relatively strong or weak in each of the sample states.

2.6 Summary of Fieldwork

The quantum of fieldwork done toward the RGNDWM evaluation study is summarized hereunder—

Activity	Total Conducted
Community Level	
In-depth Interview with Village <i>Pradhan</i> /Secretary (GP Schedule)	60
In-depth Interview VWSC member (Habitation Schedule)	240
In-depth Interview with Women beneficiaries (Household Schedule)	1440
Focus Group Discussion	240
Implementing Agency Level	
In-depth Interview with Chief Engineer (State Schedule)	5
In-depth Interview with Executive Engineer (District Schedule)	10
In-depth Interview with Asst. Executive Engineer (Block Schedule)	20

3. Physical & Financial Progress

As already mentioned in the Methodology section, a total of 5 states, one each from the five zones of the country were selected for the purpose of the study. Based on the information received from the State officials, details of physical and financial progress is presented ahead.

3.1 Physical Progress

Assessment of physical progress of the 5 study states was made in respect of the coverage status, particularly the proportion of fully covered habitations. Accordingly, during our visit to the study states and discussion with the State officials, data on habitation coverage was collected from them.

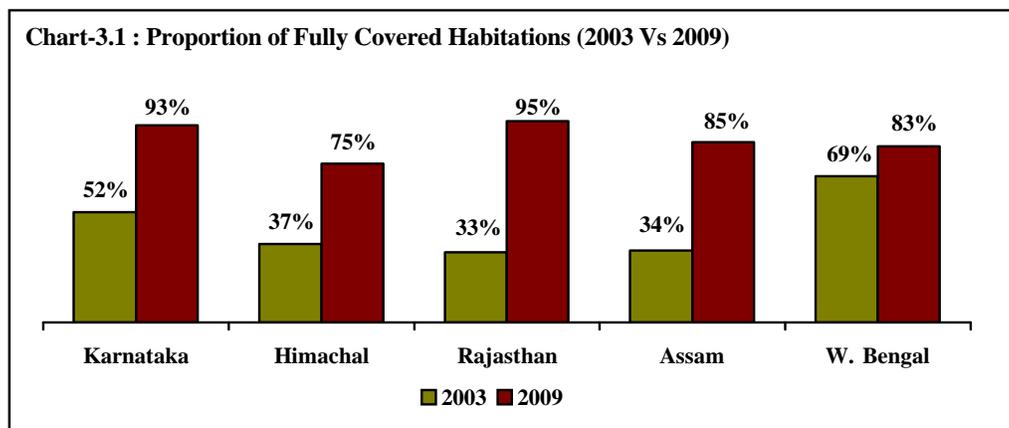

Fully Covered Habitations	
<p><i>The criteria for a habitation to be considered as 'Fully Covered' are — (a) 40 litres of safe drinking water per capita per day (lpcd) and additional 30 lpcd for cattle in the Desert Development Program Areas;(b) one hand pump or stand post for every 250 persons; and (c) the water source should exist within the habitation or within a distance of 1.6 km. in the plains and within 100 metres elevation in the hilly areas.</i></p> <p><i>Drinking water is defined as safe if it is free from bacteria contamination, chemical contamination viz. fluoride, iron, arsenic, nitrate, brackishness in excess or beyond permissible limits.</i></p>	

Based on the Habitation Survey-2003 and the data collected from the State officials, a comparative analysis of the total number of habitations and the proportion of them that are fully covered (FC) is presented in the following table.

Table-3.1 : Comparative Habitation Coverage — 2003 Vs 2009

States	Habitation Coverage (2003)			Habitation Coverage (2009)		
	Total Habs	FC	%	Total Habs	FC	%
Karnataka	51543	27021	52.4%	59630	55244	92.6%
Himachal	51848	19183	37.0%	51868	38983	75.2%
Rajasthan	121133	40342	33.3%	122250	116023	94.9%
Assam	80468	27300	33.9%	86976	73582	84.6%
W. Bengal	96242	66833	69.4%	96265	79659	82.7%

As can be seen from the chart alongside, between the period 2003 and 2009, all the 5 states have registered a good physical progress in terms of increased level of fully covered (FC) habitations. Among the 5 states, the proportion of fully covered habitations in the states of Rajasthan and Assam is found to be quite impressive, with an increase of 62 and 51 percentage points, respectively.

3.2 Financial Progress

Based on the financial data received from the study states, the State-wise analysis of the proportion of funds utilized is presented in the following table.

Fund Utilization (%)

States	Released (Rs. in lakhs)	Utilized (Rs. in lakhs)	Utilized %
Karnataka (6 Years — 2003-04 to 2008-09)	247908.47	*	-
Himachal Pradesh	*	*	-
Rajasthan (6 Years — 2003-04 to 2008-09)	612614.2	559086.7	91.2%
Assam (6 Years — 2003-04 to 2008-09)	145292.8	144002.4	99.1%
West Bengal (3 Years — 2004-05 to 2006-07)	91215.0	71434.5	78.3%

*Figures Not Available

As can be seen, while the financial progress of Rajasthan is over 90%, it is close to 100% for the State of Assam. However, the performance of the State of West Bengal has not been as good. The 3-year average of the proportion of funds utilized for this State is found to be less than four-fifth (78%).

4. Respondents' Profile — Household Survey

4.1 Respondents' Profile — Household Survey

Access to drinking water has special implications for women and children. The responsibility for fetching water for household needs, sometimes over long distances, is invariably assigned to women or girls. Accordingly, during the household survey, from each sample household, a woman respondent was purposively selected for administering the questionnaire. In case, a woman respondent was not available at the time of survey, the questionnaire was administered to the male respondent.

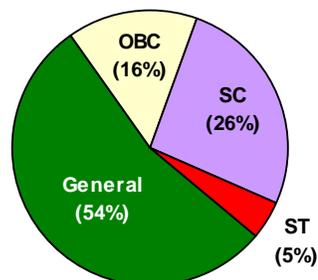

Gender-wise profile of the respondents presented in the table alongside shows that overall, an overwhelming majority (85%) of the respondents were females. Among the 5 states, Karnataka and Assam stand out where almost all (96% and 99%, respectively) respondents were females.

Table-4.1 : Gender Profile

Category	n	Female	Male
Overall	1439	84.6%	15.4%
Karnataka	288	95.8%	4.2%
Himachal	288	67.7%	32.3%
Rajasthan	287	75.6%	24.4%
Assam	288	98.6%	1.4%
West Bengal	288	85.4%	14.6%

Equitable access to safe drinking water to all sections of the society is acknowledged as important development goal of the Rajiv Gandhi National Drinking Water Mission (RGNDWM). Accordingly, care was taken to ensure that all sections of the society had due representation while selecting the households in each of the sample habitations. The social caste-wise analysis

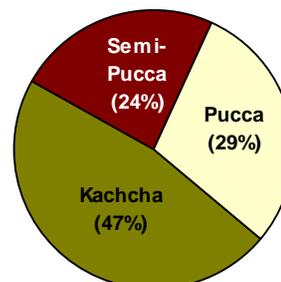

Chart-4.1 : Social Caste-wise Profile (n=1440)

of respondents presented in the chart alongside corroborates our efforts in this regard.

During the household survey, information was also recorded with respect to the type of housing of the respondents. The analysis is presented in the chart alongside. As quite expected, especially in the context of rural settings, nearly half (47%) of the sample households were 'kachcha'. The proportion of 'pucca' households stood at less than one-third (29%).

Chart-4.2 : Type of House (n=1440)

The analysis of the educational profile of the household survey respondents presented in the following shows that overall, two-fifth (41%) of the respondents were illiterate. Among the 5 states, the situation in Rajasthan is particularly distressing where three-fourth (75%) respondents were illiterate. Further, less than one-third (30%) of the respondents had the education level of upper primary or above.

Table-4.2 : Educational Profile of the Household Survey Respondents

Category	n	Illiterate	Up to Primary	Upper Primary	High-School	Higher Secondary & Above
Overall	1440	41.2%	28.9%	16.0%	9.6%	4.3%
Karnataka	288	40.4%	12.5%	15.7%	21.3%	10.1%
Himachal Pradesh	288	29.9%	56.6%	9.0%	4.5%	0%
Rajasthan	288	74.7%	23.3%	1.4%	0.6%	0%
Assam	288	28.6%	20.2%	30.3%	13.6%	7.3%
West Bengal	288	32.2%	31.4%	23.8%	8.0%	4.6%

5. Access to Safe Drinking Water

5.1 Access to Safe Drinking Water

The household survey data was analyzed for access to safe drinking water sources and a comparison was made between the pre-2003 and the present status. The State-wise and overall findings are presented in the following table —

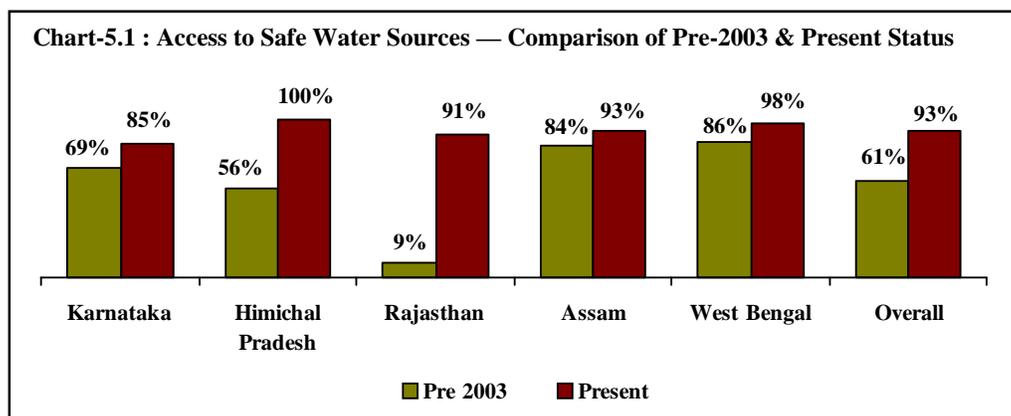

Table-5.1 : State-wise Access to Safe/Unsafe Drinking Water Sources— Pre-2003 & Present Status (n=1440)

Category	Karnataka		Himachal		Rajasthan		Assam		West Bengal		Overall	
	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date
Safe	69.1%	85.4%	55.6%	100%	9.0%	91.0%	84.0%	93.1%	85.8%	97.6%	60.7%	93.4%
Unsafe	30.9%	17.8%	44.4%	0%	91.0%	9.0%	16.0%	2.3%	14.2%	5.9%	39.3%	6.6%

Safe Sources : Tap (PWS, MWS and GLR) and Hand-pumps/Bore-Tube Wells

Unsafe Sources : Open Wells and Traditional Water Bodies (Ponds, Lakes, Rivers, Springs, etc.)

As can be seen, there has been a tremendous improvement in the rural populations' access to safe drinking water sources between the pre-2003 and the present period across all the 5 states. The improvement in this regard is found to be phenomenal in the case of Rajasthan where currently over nine-tenth (91%) of the rural households have access to safe drinking water sources as compared to less than one-tenth (9%) of them prior to 2003. During the same period, Himachal Pradesh has also registered an equally impressive improvement; currently all the households (100%) have access to safe drinking water sources as compared to less than three-fifth (56%) prior to 2003. Overall, 5 states combined, over nine-tenth (93%) of the rural population at present has access to safe drinking water sources; the improvement of 32 percentage points is a reflection of the commendable progress made under the Mission. A graphical representation of the comparative analysis of pre-2003 and present status with regard to the percentage of households having access to safe drinking water sources is presented in the following chart —

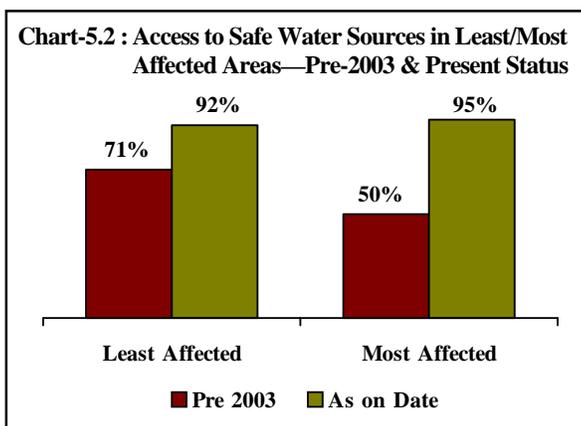

A similar analysis of household data with regard to the least and ‘most affected’ districts of the 5 states was conducted and the overall findings are presented in the following table.

Table-5.2 : Access to Safe/Unsafe Drinking Water Sources in Least & Most Affected Areas — Pre-2003 & Present Status

Category	Least Affected (n=720)		Most Affected (n=720)	
	Pre 2003	As on Date	Pre 2003	As on Date
Safe Sources	71.4%	91.8%	50.1%	95.0%
Unsafe Sources	28.6%	8.2%	49.9%	5.0%

As quite expected, compared to the households (71%) of the ‘least affected’ districts, a much smaller proportion of the households (50%) in ‘most affected’ districts had access to safe drinking water sources prior to 2003. With the advent of the Mission, the situation in the ‘most affected’ areas has improved to a point where the proportions of the households in ‘least affected’ and

‘most affected’ areas having access to safe drinking water are quite comparable (92% and 95%, respectively), as shown in the chart alongside.

5.2 Parameters of Access to Drinking Water

In order to assess the issue of access to drinking water in a holistic manner, efforts were made to elicit information from the respondents of the household survey on the following 5 key parameters.

- Safe and Round-the-year Availability
- Safe, Round-the-Year and Sufficiency
- Distance of Water Source
- Time Spent in Collecting Water
- Social Inclusion

It may be highlighted that the first 3 are the defining parameters of the ‘fully covered’ status of a habitation. Accordingly, these are discussed first.

Safe and Round-the-year Availability

The household survey findings with regard to the availability of water from safe sources on round-the-year basis, are presented in the following table —

Table-5.3 : % Households Receiving Safe and Round-the-Year Supply of Water

State	No. of Households	% Households Receiving Safe & Round-the-Year Supply
Overall	1440	65.9%
Karnataka	288	58.7%
Himachal Pradesh	288	66.0%
Rajasthan	288	70.5%
Assam	288	76.4%
West Bengal	288	58.0%

As can be seen, overall, around two-third (66%) of the households having access to safe drinking water sources are getting round-the-year supply of drinking water. Among the 5 states, Assam stands out as the best performing State with nearly four-fifth (76%) of the households are receiving round-the-year supply of water from safe sources. On the other hand, West Bengal is found to be the worst performing where two-fifth (42%) of the households have reported that they are deprived of this facility.

Safe, Round-the-Year and Sufficiency

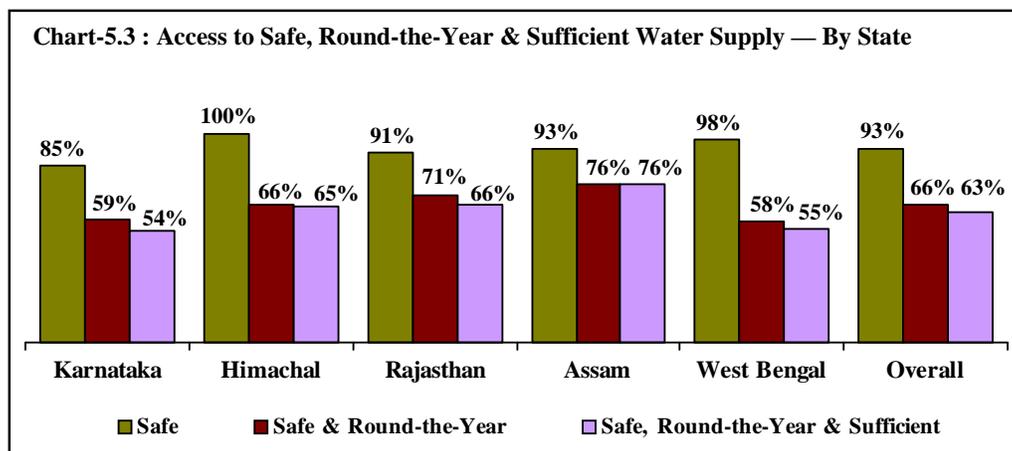

Analysis of the household survey data for the proportion of households receiving safe, round-the-year and sufficient quantity of water is presented in the following table —

Table-5.4 : % Households Receiving Safe, Round-the-Year and Sufficient Quantity of Water

State	No. of Households	% Households Receiving Safe, Round-the-Year and Sufficient Quantity of Water
Overall	1440	63.2%
Karnataka	288	53.8%
Himachal Pradesh	288	64.9%
Rajasthan	288	66.0%
Assam	288	76.0%
West Bengal	288	55.2%

As can be seen, overall, only three-fifth (63%) of the households has reported to be receiving sufficient quantity of water from safe sources on round-the-year basis. Among the 5 states, Assam stands out as the best performing State where this was reported by three-fourth (76%) of the households. On the other hand, Karnataka was found to be the worst performing State where close to half the households (46%) have reported that they were not receiving round-the-year supply of sufficient quantity of water from safe sources.

State-wise comparative analysis of households reporting safe, safe & round-the-year and safe, round-the-year and sufficient supply of drinking water is presented in the following chart.

As can be seen, although the proportion of households having access to safe water is quite high (ranging from 85% to 100%), the proportion of households reporting safe, round-the-year supply and sufficient water supply is much smaller; the difference being as high as 43 percentage points in the case of West Bengal.

Distance of Water Source

Under RGNDWM, one of the norms for a habitation to be considered as ‘Fully Covered’ is the availability of water source within the habitation or within a radius of 1.6 kms in plains and 100 meter in hilly areas. Accordingly, data was analyzed for households (having access to safe as well as unsafe water) having access to main water source within or beyond the 1.6 kms. (except Himachal Pradesh, where the criteria was within or beyond 100 meters due to the State being hilly). The findings are presented in the following table —

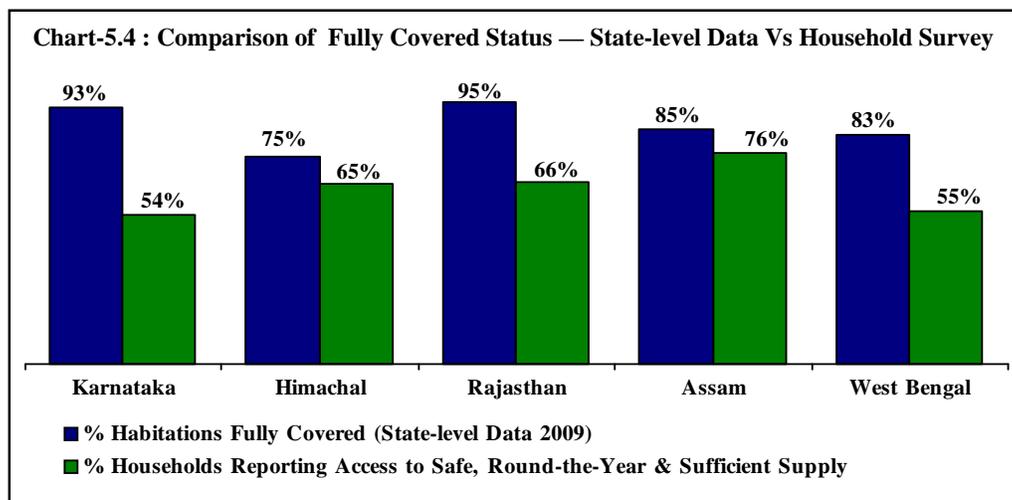

Table-5.5 : % Households having Access to Drinking Water Sources within or beyond 1.6 kms

State	No. of Households	% Households Meeting the ‘Fully Covered’ Norm
Overall	1440	99.9%
Karnataka	288	99.5%
Himachal Pradesh*	288	100%
Rajasthan	288	100%
Assam	288	100%
West Bengal	288	100%

*Distance of main water source; in case of Himachal, it is within 100 m elevation difference

As can be seen, overall, all 5 states combined, almost all the households having access to safe drinking water have reported that the main source of water was located within 1.6 kms. from their homes. As regards the households who were dependent on the unsafe drinking water sources have also reported that the main water source was located within this distance. As regards the hilly State of Himachal Pradesh, all the households surveyed have reported that the main safe source of water was located within 1.6 km or within 100 m elevation difference.

In view of all the sample households across the 5 states reporting access to safe source of water within the stipulated norm, it can be safely deduced that the proportion of households reporting access to safe, round-the-year and sufficient water supply (Table-5.4) represent the proportion of ‘fully covered’ habitations in the respective study states. The following chart presents a State-wise comparison between the proportion of ‘fully covered’ habitations based on the data received from the State officials and the proportion of households reporting access to safe, round-the-year and sufficient water supply within the stipulated distance/elevation norms.

As is evident from the chart, there are significant differentials between the ‘fully covered’ status based on the State-level data and the findings of the household survey. The difference is quite prominent in the State of Karnataka, Rajasthan and West Bengal (39, 29, and 28 percentage points, respectively).

Time Spent in Collecting Water

Access to drinking water has implications not only for health status and human development parameters but also for opportunities depending upon the opportunity cost of time. This has special implications for women and children. The responsibility for fetching water for household needs, sometimes over long distances in rural areas, is invariably assigned to

women or girls, who dropout of school to attend to these chores. Hence, the ready availability of safe drinking water lays the foundation for improvement in literacy and health indicators in communities. The household survey findings on the average time spent per day by the households in collecting water is presented in the following table —

Table-5.6 : Average Time Spent per day by Households in Collecting Drinking Water (Minutes)
(Safe: n=1345; Unsafe: n=95)

Karnataka		Himachal		Rajasthan		Assam		West Bengal		Overall	
Safe	Unsafe	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe
64	48	48	48	56	60	40	40	48	48	52	48

As can be seen, overall, the average daily time spent by the households in collecting drinking water (from safe sources) is 52 minutes. Considering the numerous constraints in the rural areas (frequent power cuts for long hours and low voltage, low water pressure, lack of proper maintenance of equipment, less than adequate number of sources, etc.), the average time of 52 minutes per day spent by the households is not much and the situation can be considered as quite satisfactory.

Water Collection from Distant Sources
District Shimoga, Block Shikaripura,
GP Sunandakoppa, Habitation-Tadasanahalli

Unreliability leading to Overcrowding
District Kolar, Block Srinivasapura,
GP & Habitation Masthenahalli

Social Inclusion

The respondents of the household survey were asked about any discrimination in access to drinking water sources so as to assess whether or not there is any social exclusion based on caste, class, gender or income in terms of access. The findings are presented in the following table —

Table-5.7 : % Households Reporting No Discrimination in Access to Drinking Water Source
(Safe: n=1345; Unsafe: n=95)

Avg. Time	Karnataka		Himachal		Rajasthan		Assam		West Bengal		Overall	
	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe	Safe	Unsafe
No	94.2%	97.6%	100%	100%	100%	100%	100%	100%	99.6	100%	98.8%	98.9%
Yes	5.8%	2.4%	0%	0%	0%	0%	0%	0%	0.4%	0%	1.2%	1.1%

It is indeed heartening to note that almost all the households across all the 5 states have reported that there is no discrimination whatsoever, with regard to access to drinking water sources. The overall situation with regard to the aforementioned 5 key parameters of access to drinking water is summarized in the following table.

Particulars	% Households
% households with access to safe and round-the-year supply	65.9%
% households with access to safe, round-the-year and sufficient supply	63.2%
% households with access to safe, round-the-year and sufficient supply within 1.6 kms	63.2%
Average time spent per day by households in collecting drinking water (Minutes)	52
% households reporting no discrimination in access to drinking water source	98.8%

5.3 Moving towards Tapped Water Supply

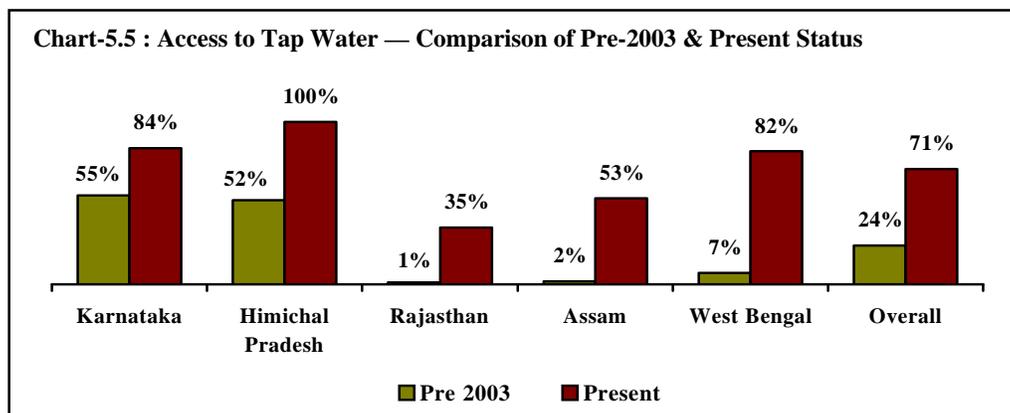

Further analysis of the household survey data with regard to the access to the main source of safe drinking water (that is tap or hand-pump/bore-tube wells) prior to 2003 and as on date was conducted and the findings are presented in the following table —

Table-5.8 : State-wise Break-up of Safe Water Sources — Pre-2003 & Present Status (n=1440)

Category	Karnataka		Himachal		Rajasthan		Assam		West Bengal		Overall	
	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date	Pre 2003	As on Date
Tap	54.9%	84.4%	52.4%	100%	1.0%	34.7%	2.1%	53.1%	6.9%	81.6%	23.5%	70.8%
HP	14.2%	1.0%	3.1%	0%	8.0%	56.3%	81.9%	40.0%	78.8%	16.0%	37.2%	22.8%

As can be seen, compared to their status prior to 2003, the proportion of households having access to tap water currently has improved quite significantly in all the 5 states. Overall, it has increased from 24% to 71% between the period prior to 2003 and as on date. During the same period, the proportion of households depending on hand-pump/ tube-bore wells has gone down, except in the State of Rajasthan. A closer scrutiny has revealed that in the case of this State, prior to 2003, 80% in Barmer district (most affected) and 84% households in Dholpur district (least affected) were receiving drinking water from open wells. Currently, the situation has changed to a point where only 8% households in Barmer and 6% households in Dholpur are using open well water, while the majority has now access to hand-pump or tap water — provided under the Mission.

A graphical presentation of the changing scenario in terms of improved access of the rural households to the tapped water supply between the period prior to 2003 and as on date in the various states is presented in the following chart.

As can be seen, there has been a drastic change, especially in the case of Rajasthan, Assam and West Bengal where the proportion of the households in 2003 having access to piped water supply was next to nothing (1%, 2% and 7%, respectively). Currently, these states have registered a significant improvement, with a substantial increase in the proportion of households having access to piped water supply (35, 53 and 82 percentage points). Among the 5 states, Himachal Pradesh and Karnataka stand out with cent percent households and over four-fifth (84%) households having access to piped water supply. Overall, all the 5 states combined, there has been an improvement from 24% prior to 2003 to the present level of 71% of the rural households having access to piped water supply.

The overall situation with regard to the key parameters of access to tapped drinking water is summarized in the following table.

Particulars	% Households
% households receiving sufficient quantity of tapped water for all purposes	86%
% households reporting round-the year availability of tapped water	66%
% households reporting regular timing of tapped water supply	85%
% households reporting convenience about the timing of tapped water supply	90%
% households reporting that tapped water is sufficient even for cattle	45%
% households reporting adequate pressure in the tapped water supply	59%

5.4 Alternate Sources of Drinking Water

As already detailed in Table-5.4, there are only 63% households that have access to safe, round-the-year and sufficient quantity of water. This implies that out of the total 1440

households, there are close to two-fifth (37%) households that have either sufficiency problem or round-the-year availability problem or both the problems. These are the households that have to depend on alternate sources of drinking water.

The following table presents an analysis of the households accessing an alternate source, in terms of whether their alternate source is safe or unsafe.

Table-5.9 : % Households having Access to Safe/Unsafe Alternate Water Sources (n=533)

Category	Karnataka	Himachal	Rajasthan	Assam	West Bengal	Overall
Safe	81.9%	17.9%	59.1%	91.5%	87.0%	69.6%
Unsafe	18.1%	92.1%	40.9%	8.5%	13.0%	30.4%

As can be seen, the alternate drinking water sources for over two-third (70%) of the households are reported to be safe, that is, for around one-third of the households (30%), the alternate drinking water source is unsafe. State-wise, an overwhelming majority of the households (82% to 92%) in the states of Karnataka, Assam and West Bengal have access to *safe* alternate sources, while in the case of Rajasthan, the alternate sources of water was unsafe ('open wells' and '*taanka*'), as reported by a significant two-fifth (41%) of the households.

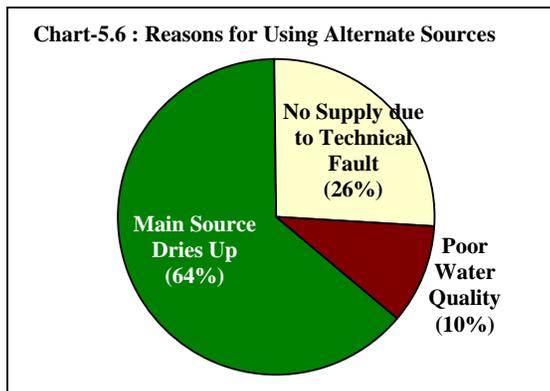

Most (92%) of households in Himachal Pradesh have reported their alternate source of water as 'springs', considered as unsafe by us. However, during discussions, it emerged that especially in summer, these households were taking water from springs as it was much cooler and better than the warm piped water supply. It may be mentioned that despite 100% households receiving sufficient quantity and 95% households receiving round-the-year supply from the main sources (tapped), almost all the households access water from springs for the aforementioned reasons.

The key parameters of access with regard to the households accessing water from alternate sources are presented in the following table.

Particulars	% Hhds
% hhds who reported to be receiving sufficient quantity from the alternate source	85%
% hhds stating the alternate source to be within 1.6 kms	97%
Average time spent per day by households in collecting water (minutes)	144

As can be seen, although alternate sources are located within the statutory distance of 1.6 kms from their homes for almost all the households (97%), average time spent per trip in collecting water from the alternate sources is found to be nearly three times as compared to that of the main source (144 minutes for alternate & 52 minutes for main sources).

During the household survey, the respondents were also asked about the reasons for using alternate sources. The overall (5 states combined) findings are presented in the chart alongside. Evidently, a large majority of the households (64%) have reported to be using alternate sources when their main sources of water have dried up, while one-fourth (26%) of them

are doing so due to non-availability of water at their main sources because of technical fault in the supply system. Further, one-tenth (10%) of them have also reported that at times, due to poor quality of water at main sources, they have to rely on the alternate water sources.

6. Water Quality

6.1 Water Quality

Satisfaction with the Water Quality

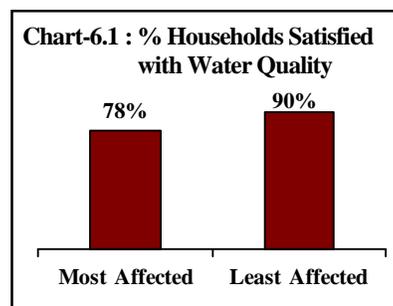

Rajiv Gandhi National Drinking Water Mission envisages provision of adequate and contamination-free drinking water on a sustainable basis to the rural population. Accordingly, during the household survey, information was elicited with regard to satisfaction with the water quality of the main water sources. The findings are presented in the following table —

Table-6.1 : % Households Satisfied with the Water Quality of Main Source (n=1440)

Quality	Karnataka	Himachal	Rajasthan	Assam	West Bengal	Overall
Satisfactory	96.9%	100%	50.5%	88.9%	84.5%	84.2%
Unsatisfactory	3.1%	0%	49.5%	11.1%	15.5%	15.8%

It is encouraging to note that overall, an overwhelming majority of the households (93%) have reported to be satisfied with the water quality. Among the 5 states, water quality is a major issue only in the State of Rajasthan, as reported by half the households (50%) surveyed in the State.

Further analysis has revealed that almost all these households belonged to the ‘most affected’ district Barmer. It may be highlighted that overall, around four-fifth (78%) of the households in the 5 ‘most affected’ districts have reported that the water quality of their main sources was satisfactory. With 90% households in the ‘least affected’ districts satisfied with the water quality of the main sources, there is not much difference between the least and ‘most affected’ districts in terms of water quality as perceived by the households.

During the discussions with the respondents of the household survey as well as with the focus group participants, the major quality problems reported in some of the states are presented hereunder —

Major Water Quality Problems of Main Sources as Reported by the Households	
☛	<i>Red color of water</i> — (reported mainly in West Bengal and Assam)
☛	<i>Bad taste/Salinity</i> — (reported mainly in Rajasthan and Karnataka)
☛	<i>Dirt Particles</i> — (reported mainly in Karnataka, Assam and West Bengal)

“The water that is supplied under the Scheme ..., that is very saline. For this, nothing has been done. People in the village do not use this water for drinking or cooking.”

FGD Participants, Dist.-Barmer, Block-Sindari, Rajasthan

“Water is dirty and its color is brownish. We leave water in the bucket for few hours so that dirt settles down and then we use it. For drinking purpose, we take water from open well.”

FGD Participants, Dist.-Bankura, Block-Bankura-2, West Bengal

“In the village, there is this problem of red color and bad smell. Mostly people avoid this water and take water from other sources.”

FGD Participants, Dist.-Nagaon, Block-Koliobar, Rajasthan

A similar analysis with regard to satisfaction with the quality of water was also conducted for the alternate sources. The findings are presented in the following table —

Table-6.2 : % Households Satisfied with the Water Quality of Alternate Source (n=1440)

Quality	Karnataka	Himachal	Rajasthan	Assam	West Bengal	Overall
Satisfactory	91.2%	98.5%	43.8%	49.1%	72.5%	71.0%
Unsatisfactory	8.8%	1.5%	56.2	50.9%	27.5%	29.0%

As can be seen, overall, 71% of the households have reported the water quality from the alternate sources to be satisfactory. Among the 5 states, water quality of the alternate sources is found to be a major issue in the states of Rajasthan and Assam where majority of the respondents (56% and 51%, respectively) have reported dissatisfaction. As regards the major quality problems in different states, the details are presented hereunder —

Major Water Quality Problems of Alternate Sources as Reported by the Households
☛ <i>Red color of water</i> — (reported mainly in West Bengal, Assam and Karnataka)
☛ <i>Bad taste</i> — (reported mainly in Rajasthan, West Bengal and Karnataka)
☛ <i>Dirt Particles</i> — (reported mainly in Karnataka, Assam and West Bengal)

Provision of Water Testing Kits to Gram Panchayats

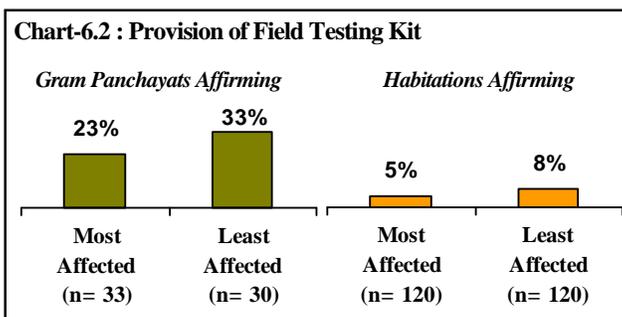

National Rural Water Quality Monitoring & Surveillance Program, the Village Water & Sanitation Committee (VWSC) in each Gram Panchayats is required to identify and test all sources of drinking water in their respective areas. For the purpose, the Gram Panchayats are provided with Field Testing Kits. During our interaction with the *Pradhans* of the sample Gram Panchayats, they were asked about provision of these kits. The findings are presented in the following table —

Table-6.3 : Gram Panchayats Reporting the Provision of Field Testing Kit (n=63)

Provision of Kits	Karnataka	Himachal	Rajasthan	Assam	West Bengal	Overall
Yes	11	3	3	1	0	18 (29%)
No	1	9	9	11	12	42 (71%)

It is disheartening to note that out of the 63 sample Gram Panchayats, only 18 have reported about being provided with the field-testing kit. Surprisingly, none of the 14 sample Gram Panchayats of West Bengal and only 1 Gram Panchayat in Assam has reported affirmatively in this regard.

Ironically, as shown in the chart alongside, the proportion of GPs provided with the field testing kits is much smaller for the ‘most affected’ districts as compared to the ‘least affected’ ones (23% vs 33%). When the issue was probed from the respondents of

the habitation survey, the overall situation was found to be much worse; with only 8% of the 240 habitations reporting the provision of field testing kits in their areas. Once again, the trend was same, with the proportion of respondents in ‘most affected’ districts responding in affirmation about the provision of field testing kit being much smaller (5%) than that of those in the ‘least affected’ districts (8%).

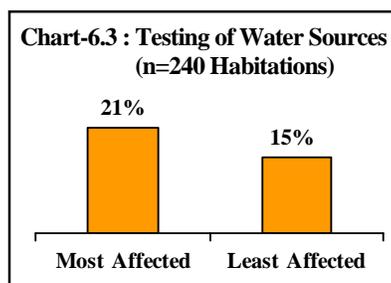

Testing of Water Sources by Technical Person

During the habitation survey, the respondents were asked if the water sources in their areas have been tested by a technical person. The findings are presented in the following table —

Table-6.4 : Testing of Water Sources in Habitations by Technical Personal (n=240 Habitations)

Water Testing	Karnataka	Himachal	Rajasthan	Assam	West Bengal	Overall
Yes	33%	32%	15%	17%	8%	21%
No	67%	68%	85%	83%	92%	79%

Once again, the results are disheartening. Overall, the respondents in four-fifth (79%) of the habitations have reported in negative about the testing of water sources. Further analysis has revealed that even in the case of ‘most affected’ districts, water sources have not been tested in three-fourth (76%) of the 120 habitations, as reported by the respondents of the habitation survey.

Field Testing Kit provided to Gram Panchayats

Efforts made by Gram Panchayat/VWSC to Maintain Water Quality of Sources

In order to ensure contamination free water supply in adequate quantity on round-the-year basis, it is highly desirable that Village Water & Sanitation Committees (VWSC) in Gram Panchayats are playing a proactive role. In this context, during the habitation survey, the respondents were asked if any efforts were made by the Gram Panchayats/VWSC with regard to maintaining the water quality of sources in their habitations. The findings are presented in the following table —

Table-6.5: Efforts made by GP/VWSC to Maintain Water Quality of Sources (n=240 Habs)

Water Testing	Karnataka	Himachal	Rajasthan	Assam	West Bengal	Overall
Yes	17%	4%	0%	0%	4%	5%
No	83%	96%	100%	100%	96%	95%

As is evident, overall (5 states combined), respondents of only a miniscule proportion (5%) of the 240 sample habitations have reported affirmatively about Gram Panchayat/VWSC making any effort to maintain water quality of sources in their areas. The situation was found to be more or less same in both the ‘most affected’ as well as the ‘least affected’ districts (4% and 6%, respectively). When probed about the efforts made, a number of responses were received from the 12 habitations. The details are presented hereunder —

Efforts made by Gram Panchayat/VWSC to Maintain Water Quality of Sources (n=12 Habs)	
Details	No. of Habitations (State)
☛ Water sources are regularly monitored by GPs	7 (Karnataka-6, West Bengal-1)
☛ Water sample sent by GPs for analysis	1 (Karnataka)
☛ Bleaching powder treatment of wells	2 (Karnataka-1, Himachal-1)
☛ Cleaning is done around water source	1 (Himachal Pradesh)
☛ Hand-pumps with poor quality water replaced with new ones	1 (West Bengal)

Trainings on Water Quality Monitoring and Surveillance

As per the State, district and block level records and discussions with the concerned officials, various trainings under water quality monitoring and surveillance were conducted at District, Block and Gram Panchayat levels. At the grassroot level, Gram Panchayat secretary, watermen, teachers, Anganwadi Workers and ANMs have been provided trainings.

When probed from the village *Pradhans* about grassroot workers having received any training, the *Pradhans* of only 23 out of the 63 sample GPs responded in affirmation, as shown in the table alongside. According to them, training was provided on quality, monitoring and sanitation & hygiene issues. Among the 5 states, Karnataka stands out with all the 12 sample GPs reporting about the provision of training to grassroot workers.

Table-6.6 : Training received by Grassroot Workers in GP

Category	n	Yes	No
Overall	63	23	40
Karnataka	12	12	0
Himachal Pradesh	12	3	9
Rajasthan	13	2	11
Assam	12	4	8
West Bengal	14	2	12

Further, when probed about the issue of women participation in trainings, it emerged that in a large majority of the Gram Panchayats (50 out of 63), no woman has received any training. Among the 5 states, Karnataka stands out where 7 out of the 12 sample GPs have mentioned about women having received training. Considering that the responsibility of collecting water lies mainly with the females of the households, the aforementioned findings are quite disheartening.

Table-6.7 : Training received by Women in GP

Category	n	No. of GPs where —			
		No Women Trained	1-2 Women Trained	3-5 Women Trained	5-10 Women Trained
Overall	63	50	4	7	2
Karnataka	12	5	0	6	1
Himachal	12	12	0	0	0
Rajasthan	13	11	2	0	0
Assam	12	8	2	1	1
W. Bengal	14	14	0	0	0

7. Operation & Maintenance

7.1 Functional Water Sources

Under Operation & Maintenance (O&M), efforts were made to collect information on various issues from the different stakeholders. We began by assessing the current status of the functional water sources (hand-pumps and tapped water supply system) in the study areas. As shown in the table alongside, over two-third (70%) of the hand-pumps and overwhelming majority (91%) of the tapped water supply sources were functional as reported by the respondents of the habitations survey.

% Functional Water Sources — As Reported by Habitations	
Water Source	% Functional
Hand-pumps	70.4%
Tapped Supply Sources	91.4%

“The hand-pump installed under the Scheme is lying defunct for past two years and people in the village have to collect water from private tube well located 2 kms. away. Department have not bothered about its repair. Panchayat has also not made any arrangement for this problem.”

FGD Participants, Dist.-Barmer, Block-Chohatan, Rajasthan

“There is only one stand-post in the village provided under the Scheme. This is not working for more than two years now;nothing has been done by the department.”

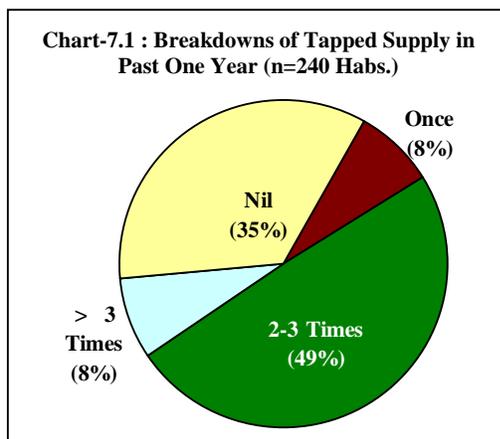

FGD Participants, Dist.-Hawrah, Block-Uluberia-2, West Bengal

Considering that a significant one-third of the hand-pumps were non-functional, the respondents of the habitation survey were probed about the reasons for the same. According to the respondents of around a significant one-fifth (18%) of the sample habitations, the hand-pumps had become defunct mainly due to ground water depletion. This problem was found to be pronounced mainly in the states of Karnataka and Rajasthan, as reported by a significant proportion of habitations (54% and 25%, respectively). The other major reason for the defunct hand-pumps was cited as lack of proper maintenance, as reported by the respondents of 16% habitations.

“In this Panchayat area, hand-pump scheme is not successful because water level has gone down to very deep level. Government should construct GLR for water supply in this area.”

FGD Participants, Dist.-Barmer, Block-Chohtan, Rajasthan

As already mentioned, there has been a continuing focus on increasing the tapped water supply in rural areas and currently, three-fifth (60%) of the households have access to tapped water supply. Accordingly, during the habitation survey, the respondents were asked about the frequency of breakdowns of the tapped water supply. The findings presented in the chart alongside show that in case of one-third (35%) of the habitations, there was no breakdown reported in the past one year, while around half (49%) have reported 2-3 times breakdown in the past one year. In the context of the rural settings and other constraints, the overall situation can be said to be satisfactory.

7.2 Responsibility of O&M

When probed about the issue of operation & maintenance of the water supply system created under the Mission, an overwhelming majority (93%) of the households were of the view that it was the sole responsibility of the

Table-7.1 : Responsibility of O&M — Households' Views

Category	n	Communi nity	Govt.	Don't Know/ Can't Say
Overall	1422	4.8%	93.1%	2.1%
Karnataka	283	7.1%	91.8%	1.1%
Himachal	288	12.2%	81.9%	5.9%
Rajasthan	286	1.7%	96.9%	1.4%
Assam	282	0.4%	97.9%	1.7%
West Bengal	283	2.5%	97.1%	0.4%

Government, indicating their unwillingness to be involved in O&M. As shown in the table alongside, overall, only a small proportion (5%) of the households was of the view that O&M should be the responsibility of the community. Among the 5 states, Himachal Pradesh stands out with the proportion of such households being the highest (12%). *When probed about the existence of any committee in their village/habitation that is responsible for maintenance of water sources, almost all the households (99%) responded in negative.*

During the focus group discussions, in most of the habitations across all the 5 study states, FGD participants reported that there was no community involvement in operation & maintenance of the scheme in their villages.

“Operation & maintenance is done by PHED. There is no community participation in O&M of the scheme.”

FGD Participants, Dist.-Nagaon, Block-Binnakhandi, Assam

As quite expected, the proportion of households willing to pay for the operation & maintenance of the water supply system was found to be very small (8%), as shown in the table alongside. Unwillingness of 92% of the households to pay for the maintenance of water supply system was corroborated by village *Pradhans* of over half (56%) of the sample GPs; they mentioned prevailing poverty among the community as the main reason for their unwillingness. *Pradhans* of only one-fourth (26%) of the GPs were of the view that the communities in their respective areas would be able to pay some amount (Rs. 10/- to Rs. 50/- per month) towards O&M, while the *Pradhans* of around one-fifth (18%) of the sample GPs mentioned that the community in their areas considered O&M as the responsibility of the GPs. Among the 5 states, Himachal Pradesh stands out with one-fourth (25%) of the households willing to pay for O&M.

Table-7.2 : Hhds Willing to Pay for O&M

Category	n	Yes	No
Overall	1415	8.3%	91.7%
Karnataka	287	10.5%	89.5%
Himachal	286	25.2%	74.8%
Rajasthan	280	2.5%	97.5%
Assam	278	0%	100%
West Bengal	284	3.2%	96.8%

7.3 Role of GPs in O&M of Water Supply System

The table alongside presents the findings on the capability of Gram Panchayats to take-up O&M of various drinking water sources, as reported by the village *Pradhans*. As can be seen, over half of the Gram Panchayats have expressed their inability to take the responsibility of O&M. Among the 5 states that have reported to be capable, Karnataka stands out where *Pradhans* of all the sample Gram Panchayats have stated that they are capable to take this responsibility.

Table-7.3 : Capability of GPs to take-up O&M

Category	n	Yes	No
Overall	63	30	33
Karnataka	12	12	0
Himachal Pradesh	12	6	6
Rajasthan	13	2	11
Assam	12	7	5
West Bengal	14	.3	11

“Operation & maintenance is done by Gram Panchayat and for this purpose, one Waterman is appointed who is responsible to the all O&M works. Cost of small repairs is borne by GP, big repairs are done by department.”

FGD Participants, Dist.-Kolar, Block-Malur, Karnataka

On the issue of formal handing over of O&M of the assets created under the Mission, a large majority of the Gram Panchayats (50 out of 63) have responded in negative. Among the 5 states, Karnataka stands out where the village *Pradhans* of all the 12 sample GPs have mentioned that O&M has been formally handed over to GPs (Table alongside).

Table-7.4 : Formal Handing Over of O&M to GPs

Category	n	Yes	No
Overall	63	13	50
Karnataka	12	12	0
Himachal Pradesh	12	1	11
Rajasthan	13	0	13
Assam	12	0	12
West Bengal	14	0	14

The findings on the present status with regard to the entity responsible for the operation and maintenance of the various drinking water sources in the sample Gram Panchayats are presented in the table alongside. As can be seen, in a large majority of the GPs (44 out of

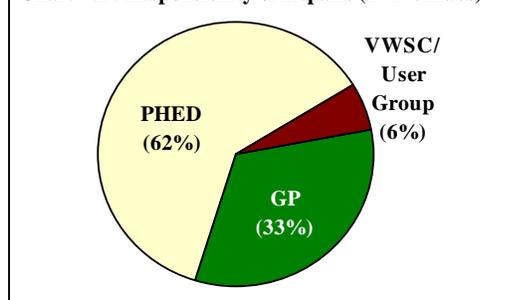

Table-7.5 : Responsibility of O&M — Present Status

Category	n	PHED	GP	VLWSC
Overall	63	44 (69.8%)	16 (25.4%)	3 (4.8%)
Karnataka	12	0	12	0
Himachal	12	12	0	0
Rajasthan	13	13	0	0
Assam	12	10	0	2
West Bengal	14	9	4	1

63), the implementing agency (PHED) has the responsibility of O&M, as reported by the village *Pradhans*. Further, in 16 Gram Panchayats, the responsibility of O&M lies with the GPs. As already mentioned, with formal handing over of the O&M, all the 12 sample GPs in the State of Karnataka have the responsibility of O&M. Besides, 4 GPs in West Bengal have also reported to be having O&M responsibility with them. As regards the remaining 3 GPs, the O&M responsibility lies with the Village Level Water & Sanitation Committee (VLWSC). It may be highlighted that major breakdown repairs are taken-up by the PHED only.

The issue with regard to the entity responsible for the O&M of the various drinking water sources was also discussed with the habitation survey respondents. The findings are presented in the chart alongside. As can be seen, these are more or less similar to the aforementioned Gram Panchayat level findings.

Chart-7.2 : Responsibility of Repairs (n=240 Habs)

7.4 Problems faced by Gram Panchayats

During the course of discussion with the *Pradhans* of the sample Gram Panchayats, information was elicited with regard to the various problems faced by them with regard to the water supply in their respective Panchayats. Out of the 63 sample GPs, 41 of them stated

that they did not have any problem. As regards the remaining 22 GPs, the details of the problems as reported by the *Pradhans* are presented in the following table.

Problems Faced by Gram Panchayats	
☛ Ground water depletion	6 Gram Panchayats (Most Affected-5; Least Affected-1) (Karnataka-5, Assam-1)
☛ Lack of funds and consequent shortage of PSPs and less coverage	3 Gram Panchayats (Karnataka-1, Assam-2)
☛ Household connections are not picking up being too expensive due to non availability of pipe lines as well as low income level of community	2 Gram Panchayats (Himachal Pradesh-2)
☛ Non availability of land for laying pipelines	7 Gram Panchayats (Himachal Pradesh-6, Rajasthan-1)
☛ Quality Problems	3 Gram Panchayats (In Most Affected) (Assam-3)
☛ Irregular electricity supply	1 Gram Panchayat (Assam-1)

As can be seen, ground water depletion and quality problems were reported from the Gram Panchayats of Karnataka & Assam and barring just one GP, all the other GPs are from the ‘most affected’ districts. There were 3 GPs where the *Pradhans* have reported about the shortage of funds due to which adequate number of public stand posts could not be installed and as a result, coverage is adversely impacted. We also came across 7 GPs where the *Pradhans* have reported about facing problems with regard to laying of pipelines that pass through the private land. According to them, people were generally disinclined to permit laying of pipelines on their land.

Efforts were also made to capture the views and suggestions of the respondents of the household survey with regard to water supply in their areas. The findings are presented in the following table —

Suggestions by Households — Overall (5 States Combined)	
☛ % of households saying hand-pumps to be installed	17.8% (Mostly in Rajasthan)
☛ % of households saying piped stand-posts to be increased	21.5% (All states)
☛ % of households saying maintenance to be improved	8.8% (All states)
☛ % of households saying quality to be improved	15.0% (Rajasthan, Assam & W. Bengal)
☛ % of households saying water supply to be regular with increased timing	19.9% (All states, except Rajasthan)
☛ % of households saying pressure to be increased	6.3% (All states, except Rajasthan)

As can be seen, overall, a significant proportion of households (18%), mostly in Rajasthan felt the need for the provision of more hand-pumps, while over one-fifth (22%) expressed the need for more piped stand posts in their areas. Among the other major suggestions, improving maintenance and quality of water emerged as the prominent suggestions, as expressed by 15% and 20% of the households, respectively.

8. Water Tariff

8.1 Water Tariff

As per the household survey, 14.6% (total 210) of all the households were found to be having tap connections. It may be mentioned that in Rajasthan, none of the sample households have reported to be having tap connection.

Discussions with the *Pradhans* of the sample Gram Panchayats revealed that overall, in less than half (30 out of 63) of the GPs, the households have been provided tap connections. *Although, as shown in the table alongside, tap connections are provided to some households in 2 out of the 13 sample GPs in Rajasthan, the sample households in the sample habitations in these GPs do not have tap connections.*

Table-8.1 : Tap Connections in GPs

Category	n	GPs With Tap Conn.
Overall	63	30
Karnataka	12	9
Himachal	12	12
Rajasthan	13	2
Assam	12	6
W. Bengal	14	1

The table alongside presents the proportion of households having tap connection paying water charges on a regular basis. As can be seen, overall, close to nine-tenth (87%) of the households are indeed paying water charges on a regular basis. Among the 4 states, Himachal Pradesh stands out where all the households are reportedly paying water charges regularly.

Table-8.2 : Households Paying Water Charges Regularly

Category	n	Yes	No
Overall	210	87.1%	12.9%
Karnataka	83	77.1%	22.9%
Himachal	88	100%	0%
Assam	26	80.8%	19.2%
West Bengal	13	76.9%	23.1%

The issue of the payment of water charges on a regular basis was also discussed with the *Pradhans* of the sample GPs where households were reported to be having tapped water supply. According to the *Pradhans* of two-third (19 out of 30) such GPs, over four-fifth (83%) of all the households were paying water tariff on a regular basis.

The analysis of the average amount of monthly water charges per household is presented in the table alongside. The average amount is found to be lowest (Rs. 12.70/- per month per household) in Himachal Pradesh and highest (Rs. 53.80/- per month per household) in Assam. Overall, 4 states

Table-8.3 : Avg. Monthly Charges per Hhd.

Category	n	Rs.
Overall	190	22.30
Karnataka	72	22.20
Himachal	87	12.70
Assam	21	53.80
West Bengal	10	41.00

combined, the average monthly water charges per household works out to Rs. 22.30/-. The analysis of Gram Panchayat data shows more or less the same amount of average monthly

water charges per household (Rs. 23.50/-). Further, it has also been found that there is no variation in the water charges among the households belonging to the different social categories (general, scheduled caste or scheduled tribe).

It was found that an overwhelming majority (88%) of the households having tap connections had paid installation charges. This was corroborated by the village *Pradhans* of almost all the GPs (29 out of 30) where households have been provided

Table-8.4 : Avg. Installation Charge per Hhd.

Category	n	Rs.
Overall	169	644.30
Karnataka	51	532.40
Himachal	87	526.60
Assam	21	834.30
West Bengal	10	1840.00

tap connection. The analysis of the average amount of installation charges per household is presented in the table alongside. This is found to be lowest (Rs. 526.60/- per household) in Himachal Pradesh and highest (Rs. 1840.00/- per month per household) in West Bengal. Overall, 4 states combined, the average installation charges per household works out to Rs. 644.30/-.

It may be highlighted that the user charges for Public Stand Post (PSP) were collected only in the State of Karnataka, as reported by the village Pradhans of the 12 sample Gram Panchayats. According to them, the average monthly amount of water charges per household was Rs. 10/- for all sections of the society.

During discussions with the *Pradhans* of the sample GPs, it also emerged that there were instances of some household connections being disconnected due to non-payment of water tariff. While lack of civic responsibility was cited by half of them as the reason for non-payment on a regular basis, the other half was of the view that the irregular and sometimes inadequate water supply was the main reason that prompted the community members to shy away from making payment on a regular basis. Similar explanations were cited by the household survey respondents who were not paying on a regular basis.

On the issue of affordability of the water charges, it was found that overall, almost all the households (96%) across the 4 states have responded in affirmation, as shown in the table alongside. Even according to the village *Pradhans* of over two-third of the GPs (22 out of 30), the water tariff is affordable to all sections of the society.

Table-8.5 : Households Saying Water Charges Affordable

Category	n	Yes	No
Overall	187	96.3%	3.7%
Karnataka	72	93.1%	6.9%
Himachal	82	100%	0%
Assam	23	91.3%	8.7%
West Bengal	10	100%	0%

Efforts were also made to gauge the level of satisfaction among the households having tap connection with regard to the water charges paid by them vis-a-vis the quantity/quality of water supply received by them. As is evident from the analysis presented in the table alongside, almost all (95%) the households have expressed satisfaction in this regard.

Table-8.6 : Hhlds Satisfied with Water Charges

Category	n	Yes	No
Overall	189	94.7%	5.3%
Karnataka	72	90.3%	9.7%
Himachal	85	98.8%	1.2%
Assam	22	90.9%	9.1%
West Bengal	10	100%	0%

8.2 Setting-up Water Tariff — Responsibility, Basis and Community Consultation

During the discussion with the village *Pradhans* of the 30 GPs where households have been provided tap connections, it was found that in most GPs, the implementing agency (PHED) was responsible for setting-up water tariff. Whereas, wherever the supply system had been formally handed-over to the GPs, the PRI was responsible for setting-up water tariff. Similarly, in some Gram Panchayats, this was done by Village Level Water & Sanitation Committee.

When probed about the basis for setting-up the water tariff from the village *Pradhans* of GPs having this responsibility, most of them mentioned that it was done in accordance with the Government Order. On the issue of community being consulted before setting-up the water tariff, the village *Pradhans* of only one-fifth (6 out of 30) of the GPs responded in affirmation (table alongside). As regards informing the community about the water tariff, the village *Pradhans* mentioned about the use of public announcement, public display or through ‘Watermen’ for the purpose.

Table-8.7 : GPs where Community was Consulted on Water Tariff

Category	n	Yes	No
Overall	30	6	24
Karnataka	9	2	7
Himachal	12	0	12
Rajasthan	2	0	2
Assam	6	1	5
West Bengal	1	1	0

8.3 Adequacy of Water Tariff in Meeting the O&M Cost

As already mentioned, only in the State of Karnataka, the Gram Panchayats have been formally handed over the assets created under Rajiv Gandhi National Drinking Water Mission. Since these Gram Panchayats are responsible for O&M and collection of user charges, the village *Pradhans* of these GPs were asked if the amount collected from the households was enough to meet the expenditure incurred on O&M. To this, village *Pradhans* of most of the GPs mentioned that around 50% of the O&M cost is recovered from the user charges. They also mentioned that the funds are set-aside in Water & Sanitation Account for emergencies.

9. Community Participation/Existence of VWSC

9.1 Community Participation/Existence of VWSC

Community Participation : Active community involvement is envisaged under Rajiv National Gandhi Drinking Water Mission (RGNDWM) and as such, their involvement is highly desirable at every stage — from planning, to implementation, operation and maintenance (O&M) and ownership. However, as already discussed, absence of the community participation in operation & maintenance of the water supply schemes in their areas was near universal. The only instance of community involvement was reported to be in the site selection for the stand posts and the route for laying the water supply pipeline, as revealed by the participants of FGDs conducted in the sample habitations.

Existence of VWSCs : At the grass root level, the role of PRI assumes special significance in term of providing a supportive environment so as to ensure sustainable community-based drinking water supply system. During the household survey, instead of asking a direct question about the existence of VWSCs, the households were asked if they were aware about the existence of any group in the village/habitation. The analysis is presented in the following table.

Table-9.1 : Awareness about Existence of Any Group in Village/Habitation

Category	n	Health & Sanitation Committee	SHGs	Village Education Committee	Village Water & Sanitation Committee	Don't Know
Overall	1417	0.4%	16.8%	0.4%	0.7%	81.7%
Karnataka	281	0%	26.0%	0%	0.7%	73.3%
Himachal	288	1.7%	47.2%	2.1%	0%	49%
Rajasthan	279	0%	0%	0%	0%	100%
Assam	282	0%	5.6%	0%	0.4%	94.0%
West Bengal	287	0%	4.9%	0%	2.1%	93.0%

As shown in the table, over four-fifth (82%) of the sample households were found to be unaware about the existence of any group in their areas. Among the remaining households (18%), most of the respondents have mentioned about the presence of self help groups (SHGs). As regards the proportion of households aware about the Village Water & Sanitation Committee (VWSC), it has been found to be less than 1%. Further, we also came across a few households that mentioned about the existence of Health & Sanitation Committee or Village Education Committee in their areas (0.4% each).

Even during the focus group discussions, it was found that in most of the habitations across all the 5 study states, the FGD participants were unaware about the existence of Village Water & Sanitation Committee in their areas.

“No, there is no such committee in our village, we have not heard about it. ”

FGD Participants, Dist. Bankura, Block-Patrasayer, West Bengal

“Committee has not been formed because entire work is done by the workers deployed by the I&PH department.”

FGD Participants, Dist. Bilaspur, Block-Sadar, Himachal Pradesh

The households found to be aware about the existence of any group in their area were asked if they were member of any such group. The findings presented in the table alongside show that overall, around half (47%) of these households were members of any group. Since most of the households had mentioned about the existence of SHGs, it can safely be inferred that the households reporting membership to any group were referring to these SHGs.

Table-9.2 : Households Reporting Membership

Category	n	Yes	No
Overall	263	47.4%	52.6%
Karnataka	73	67.1%	32.9%
Himachal	143	38.5	61.5%
Assam	22	61.5%	38.5%
West Bengal	25	30.0%	70.3%

Further, the households reporting to be the member of any group were asked about their participation in groups' meetings. As shown in the table alongside, almost all (99%) of these households have responded in affirmation.

Table-9.3 : Member Hhds Participating in Meetings

Category	n	Yes	No
Overall	124	99.3%	0.7%
Karnataka	48	100%	0%
Himachal	55	100%	0%
Assam	15	94.4%	5.6%
West Bengal	7	100%	0%

From the gender perspective, the households were also asked about the women's representation in the existing committee/groups in their area. The findings presented in the table alongside show that according to most of the households (99%), the women's representation was either 'good' or 'fair'.

Table-9.4 : Women's Representation in Committee/ Group

Category	n	Good	Fair	Poor
Overall	123	51.3%	47.4%	1.3%
Karnataka	48	20.3%	79.7%	0%
Himachal	53	90.9%	9.1%	0%
Assam	14	35.3%	64.7%	0%
W. Bengal	8	0%	80.0%	20.0%

As regards the issues dealt by the 'groups/committees', three-fifth (58%) of the member-households have mentioned about 'fund raising' taken-up by the group/committee across the 4 states. Obviously, these households were referring to the critical activity

Issues Dealt by Committee (Multiple Responses)	% Hhds (n=124)
☛ Fund Raising	57.6%
☛ Cleaning/Protection of Water Sources	55.6%
☛ Health & Sanitation Issues	59.6%
☛ Construction of Public Latrine	3.3%

(fund raising) of the self help groups. Further, more or less a similar proportion of them mentioned 'cleaning/protection of water sources' and 'health & sanitation issues', taken-up by the group/committee mostly in the states of Karnataka and Himachal Pradesh. We also came across a few households (3.3%) in Himachal Pradesh that mentioned about construction of toilets.

The issue of formation and existence of VWSCs was also discussed with the *Pradhans* of the sample Gram Panchayats. The analysis presented in the table alongside shows that VWSCs were existing in only one-fifth (13 out of 63) of the sample Gram Panchayats. Among the 5 states, Karnataka stands out where the presence of VWSC was reported by half the sample Gram Panchayats.

Table-9.5 : Gram Panchayats having VWSC

Category	n	Yes	No
Overall	63	13 (21%)	49 (79%)
Karnataka	12	6	6
Himachal	12	1	11
Rajasthan	13	3	10
Assam	12	2	10
W Bengal	14	1	12

The *Pradhans* mentioning about the presence of VWSC in their Gram Panchayats were probed about the details of the meetings and training of the VWSC members. As can be seen from the table presented alongside, VWSC meetings were conducted only

Particulars (Multiple Responses)	No. of GPs (n=13)
☛ VWSC Meeting Conducted	9
☛ Women Attend VWSC Meeting	7
☛ SC Attend VWSC Meeting	7
☛ All VWSC Members Trained	6

in 9 out of the 13 GPs. As regards the participation of women and scheduled caste community members in the VWSC meetings, this was reported in only 7 out of the 13 GPs. Further, in only 6 out of the 13 GPs, all VWSC members have reportedly received training.

The findings with regard to the key activities of the VWSCs, as reported by the concerned *Pradhans* of their respective Gram Panchayats are presented in the table alongside. As can be seen, in 9 out of the 13 GPs, the VWSC was reportedly involved

Activities of VWSC (Multiple Responses)	No. of GPs (n=13)
☛ Decision Making	9
☛ Collection of Water Charges	6
☛ Financing & Managing O&M	6
☛ Arranging Contribution (Cash & Kind)	2
☛ Empowering Women for O&M	2

in the decision making process. Further, in 6 Gram Panchayats, VWSCs were reported to be involved in collection of water charges and financing & managing operation & maintenance. We also came across 2 Gram Panchayats whose *Pradhans* mentioned about empowering women on operation & maintenance and day-to-day affairs of the Scheme.

10. Knowledge, Practice and IEC on Hygiene & Sanitation

Interventions for providing safe drinking water can become ineffective in the absence of improved sanitation. In order to provide access to sufficient quantities of safe water, the provision of facilities for a sanitary disposal of excreta, and introducing sound hygiene behavior are of utmost importance. The ways and means by which water is collected also has an impact on its quality. It is essential to have a clean surrounding around the source to prevent contamination. Open drains and disposal of solid waste near sources of water may lead to presence of ammonia and coliform bacteria in the drinking water source. The study findings on the relevant issues are discussed ahead.

10.1 Exposure to Awareness Campaigns

Making people aware on the need to consume safe water is one of the major challenges. There are examples where despite being provided potable water by the Government, people drink water from contaminated surface sources. An integrated campaign can result in widespread information dissemination amongst the masses on all aspects of rural water supply and its related issues. This could be done by bringing about public awareness through appropriate methods, such as, folk songs, folk drama, documentary films, pamphlets, brochures, etc. GoI provides 100% grant-in aid to establish Communication and Capacity Development Unit (CCDU) in all States/UTs for the purpose of creating awareness among rural people.

During the study, Gram Panchayats, habitations and households were probed about any campaign organized in their area on water & sanitation and hygiene in their villages. The findings are presented in the following table —

Table-10.1 : Gram Panchayats, Habitations and Households Reporting Campaigns on Water, Sanitation & Hygiene

Category	GP		Habitations		Households	
	n	%	n	%	n	%
Overall	62	71.0%	239	23.8%	1430	12.5%
Karnataka	12	66.7%	48	6.3%	287	0.7%
Himachal Pradesh	12	100%	48	81.3%	282	54.6%
Rajasthan	13	69.2%	47	19.1%	286	7.7%
Assam	11	54.5%	48	10.4%	288	0%
West Bengal	14	64.3%	48	2.1%	287	0.3%

It is interesting to note that there are significant variations among the proportion of GPs, habitations and households responding in affirmation about the campaign on water & sanitation and hygiene (71%, 24% and 13%, respectively). This is probably an indication that some campaigns were organized at Gram Panchayat level, but this has not percolated to the grassroot-level, that is, the household level where information/awareness is needed the most. At the household level, barring Himachal Pradesh, the situation in the other 4 states is absolutely pathetic.

As a matter of fact, during the focus group discussion in most of the sample habitations in Assam, West Bengal, Karnataka and Rajasthan, the FGD participants have reported that no IEC campaign was taken-up in their areas.

“No, there has not been any awareness campaign in our village.”

FGD Participants, Dist. Nagaon, Block-Binna Kandi, Assam

“In our village, there was no awareness activity about water supply.”

FGD Participants, Dist. Barmer, Block-Sindari, Rajasthan

10.2 Details of Awareness Campaigns

When probed from the aware households about the details of campaigns, most of the respondents in Himachal Pradesh mentioned about Total Sanitation Campaign (TSC), while in the case of Rajasthan, most of the respondents mentioned about the Jal Rath Yatra campaign.

As detailed in Table-10.1, only 24% habitations (total 58) have reported about any campaign organized in their area. The respondents of these habitations were also probed about the details of campaigns. The findings are presented in the following table —

Details of Campaign on Water & Sanitation — As Reported by Habitations (n=58)	
☛ Information about sanitation & hygiene under TSC	42 habitations (Himachal-40, Karnataka-1, Rajasthan-1)
☛ Jal Rath Yatra/Jal Chetna Abhiyan	9 habitations (Rajasthan)
☛ Campaign by Health Deptt. on water, sanitation & pollution free environment	7 habitations (Karnataka-3, Assam-3, West Bengal-1)

As can be seen, most of the habitations have also mentioned about the Total Sanitation Campaign (42 out of 58 habitations), while Jal Rath Yatra/Jal Chetna Abhiyan was mentioned in 9 habitations of Rajasthan. We also came across 7 habitations where the

respondents mentioned about the campaign on water, sanitation & pollution-free environment conducted by the Health Department.

Similar information was received during the focus group discussions conducted in the sample habitations across the 5 study states.

“In March 2009, IPH department through block had taken-up cleanliness campaign in our village wherein cleanliness of storage tanks & natural water sources, keeping drinking water vessel covered, etc. was communicated,many people in the village had participated.”

FGD Participants, Dist. & Block-Kullu, Himachal Pradesh

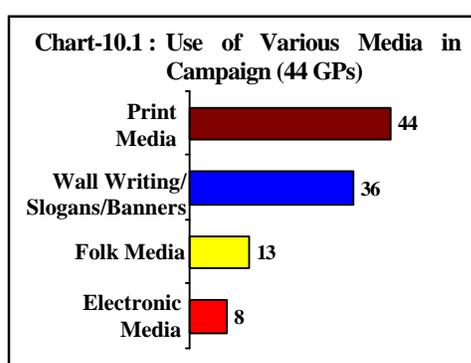

“Jal Rath Yatra in 2008 was conducted by the block officers and Panchayat members wherein information was given about clean drinking water. Around 50% people had participated in this program.”

FGD Participants, Dist. Barmer, Block-Sindari, Rajasthan

“In May this year, there was one campaign conducted by the block level Health Department. They told us about sanitation, cleanliness, hygiene and about clean water.

FGD Participants, Dist. Shimoga, Block-Shikaripura, Karnataka

When discussed with the *Pradhans* (of 71% GPs reporting campaign) about the details of awareness campaigns, they informed that various mass media, namely, print media, traditional media and folk media (folk songs, street plays & puppet show, etc.) were used for the purpose. As shown in the chart alongside, use of the print and the traditional media used in rural settings (wall writings, slogans & banners) were the two most common media used for the campaign, as mentioned by 44 and 36 *Pradhans*, respectively (who had reported about the awareness campaigns in their GPs). The use of folk and electronic media was relatively much smaller (reported by 13 and 8 *Pradhans*, respectively). The state-wise details of the various media used for campaign, as reported by the GPs are presented in the following table.

Category	Karnataka	Himachal	Rajasthan	Assam	W.Bengal
Use of Print Media in Campaign (44 GPs)					
Posters	7	10	7	6	5
Pamphlet	3	8	3	6	4
Booklet	1	1	2	1	
Traditional Media using Rural Resources (36 GPs)					
Slogan	1	10	9	1	5
Wall Writing	2	7	7	5	4
Banner		1		2	4
Exhibition			1		
Traditional Folk Media (13 GPs)					
Folk Songs		3	2		2
Street Play	1	1	5		2
Puppet Show	1				
Use of Electronic Media (8 GPs)					
Radio	2		2		
TV	2				
Documentary or Short Film		2	2		

The *Pradhans* were also asked about the details of participation of the village population, including that of women in the awareness campaign. The findings are presented in the table alongside. Apparently, overall, three-fifth (60%) of the GP

Table-10.2 : % Population in GP Attending Campaign

Category	GPs	% Population	% Women
Overall	44	59.7%	36.5%
Karnataka	8	61.9%	36.9%
Himachal	11	60.3%	43.3%
Rajasthan	9	45.0%	15.6%
Assam	7	69.3%	46.4%
West Bengal	9	64.0%	39.9%

population had participated in the various campaigns, as reported by the *Pradhans* of the 44 GPs. Further, it is also heartening to note that a significant two-fifth (37%) of the women had also participated in the awareness campaigns.

10.3 Source of Information on Safe Drinking Water

Interpersonal Communication (IPC): On the issue of awareness generation among the communities by way of interpersonal communication (IPC), the households were asked a direct question if anybody had informed them about safe drinking water. The findings contained in the table alongside presents a dismal picture, with only an abysmally small proportion of households responding in affirmation about somebody providing them information on safe drinking water.

Table-10.3 : IPC on Safe Drinking Water

Category	n	Yes	No
Overall	1438	7%	93%
Karnataka	288	11%	89%
Himachal	288	14%	86%
Rajasthan	287	5%	95%
Assam	288	5%	95%
West Bengal	287	3%	97%

Further, the households were also asked if they were visited by ASHA/ Anganwadi Workers or any other person for providing information on water, sanitation & hygiene. The findings are once again distressing, with less than one-tenth (7%) of the households responding in affirmation in this regard. Among the 5 states, Himachal Pradesh stands out where close to one-fourth (23%) of the respondents have mentioned that these functionaries were indeed visiting them for providing information on water, sanitation & hygiene.

Table-10.4 : Hhd visits by ASHA/AWW/Others in the past One Month for Water Sanitation & Hygiene Info

Category	n	Yes	No	Don't Know/ Can't Say
Overall	1437	7.0%	84.1%	8.9%
Karnataka	288	3.8%	87.5%	8.7%
Himachal	288	23.3%	70.8%	5.9%
Rajasthan	288	4.2%	79.8%	16.0%
Assam	287	2.1%	93.7%	4.2%
West Bengal	286	1.4%	88.8%	9.8%

Main Source of Information on Personal & Household Hygiene:

During the household survey, the respondents were asked about their main source of information on personal and household hygiene. The findings presented in the table alongside show that an

Table-10.5 : Main Source of Information on Personal & Household Hygiene

Category	n	Radio or TV	News Paper	ANM, ASHA or AWW	Villagers
Overall	1425	88.2%	1.8%	8.2%	1.8%
Karnataka	285	95.8%	1.4%	1.7%	1.1%
Himachal	287	93.1%	0.4%	4.6%	1.9%
Rajasthan	286	56.3%	4.9%	33.6%	5.2%
Assam	287	97.8%	2.2%	0%	0%
W. Bengal	280	97.9%	0%	1.0%	1.1%

overwhelming majority (88%) of the households are getting relevant information from radio or television. Among the 5 states, the State of Rajasthan stands out where ANM, ASHA or Anganwadi Worker are reported by one-third (34%) households as the main source, while only around three-fifth (56%) have reported radio or TV as their main source of information on personal and household hygiene. As regards the other 4 states, radio or TV is the main source of the information for almost all the households.

10.4 Training of VWSC Members/Teachers on Hygiene Education

During the habitation survey, the respondents were probed on the issue of training of VWSC members or teachers on hygiene education. The findings are presented in the table alongside. As can be seen, respondents in almost all the habitations have denied about the provision of any such training to the VWSC members or teachers. Since in most cases VWSCs are not formed, these findings are not surprising.

Table-10.6 : Training on Hygiene Education

Category	n	Yes	No
Overall	240	2.5%	97.5%
Karnataka	48	4.2%	95.8%
Himachal	48	0%	100%
Rajasthan	48	2.1%	97.9%
Assam	48	4.2%	95.8%
West Bengal	48	2.1%	97.9%

10.5 Awareness about Diseases Caused by Unhygienic Conditions

The table alongside presents the level of awareness among the households with regard to the diseases caused by unhygienic conditions. As can be seen, three-fourth (75%) of the households are indeed aware in this regard. Among the 5 states, Himachal Pradesh stands out with the highest level of awareness (96%), whereas in West Bengal, less than three-fifth (55%) of the households are aware. Surprisingly, in this State, a sizable proportion of the respondents (36%) were unable to provide a clear answer on this important issue.

Table-10.7 : Awareness about Diseases Caused by Unhygienic Conditions

Category	n	Yes	No	Don't Know/ Can't Say
Overall	1433	74.7%	6.8%	18.5%
Karnataka	285	70.2%	10.2%	19.6%
Himachal	288	96.2%	0.7%	3.1%
Rajasthan	286	68.9%	12.2%	18.9%
Assam	288	83.0%	2.8%	14.2%
West Bengal	286	55.2%	8.4%	36.4%

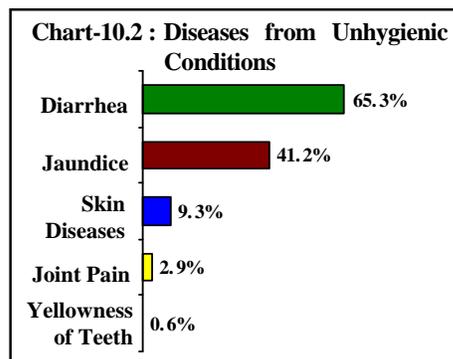

It may be highlighted that 'most affected' districts have fared better than the 'least affected' ones in terms of the level of awareness (78% as against 72%). These findings were corroborated during the focus group discussion conducted in the sample habitations across the 5 study states.

Further, according to most of the *Pradhans* of the 63 sample Gram Panchayats as well as most of the 240 sample habitations, the community is generally quite aware about the link between poor quality of water and diseases. Once again, the level of awareness was higher among the households in 'most affected' as compared to the 'least affected' districts. The households that were found to be aware were further probed about the type of diseases caused by the unhygienic conditions. The findings are presented in the following table.

Table-10.8 : Details of Diseases due to Unhygienic Conditions — As Reported by Households

Category	n	Diarrhea	Jaundice	Skin Diseases	Joint Pain	Yellowness of Teeth
Overall	1089	65.3%	41.2%	9.3%	2.9%	0.6%
Karnataka	202	78.7%	56.4%	0%	0%	0%
Himachal	277	59.2%	15.9%	0%	0%	0%
Rajasthan	209	23.9%	20.6%	48.3%	15.3%	3.3%
Assam	240	87.9%	50.4%	0%	0%	0%
West Bengal	161	78.9%	78.9%	0%	0%	0%

As can be seen from the table, diarrhea has emerged as the most commonly occurring disease resulting from the unhygienic conditions, followed by jaundice, as reported by 65% and 41% of the households, respectively. Further, in Rajasthan, around half the households (48%) have mentioned skin disease, 15% joint pain and 3% have mentioned yellowness of teeth, indicating the presence of excessive 'fluoride' in the water sources used by these households. The overall picture with regard to the diseases caused by unhygienic conditions, as perceived by the households is presented in the chart alongside.

10.6 Availability of Toilets

It is well established that mere access to safe drinking water does not ensure prevention of diseases; appropriate sanitation and hygiene practices also play a crucial role in ensuring good health. Accordingly, during the household survey, information was elicited about the availability of toilets in the households. The findings presented in the table alongside show that overall, only a little over two-fifth (43%) of the households have toilets. The situation is particularly pathetic in Rajasthan where the availability of toilet was reported by only 3 out of the 287 households (1%), indicating an utter failure of the Total Sanitation Campaign (TSC) in the two sample districts of this State.

Table-10.9 : Availability of Toilets in Hhlds

Category	n	Yes	No
Overall	1435	42.7%	57.3%
Karnataka	287	47.0%	53.0%
Himachal	287	65.9%	34.1%
Rajasthan	287	1.0%	99.0%
Assam	286	64.3%	35.7%
West Bengal	288	35.4%	64.6%

10.7 Practice of Open Defecation

As regards the practice of open defecation, the findings presented in the table alongside show that overall, only 16% of the 237 habitations are 'fully free', while four-fifth (80%) of the habitations are reported to be 'somewhat free' from open defecation. With only two-fifth

Table-10.10 : Habitations Free from Open Defecation

Category	n	Fully Free	Somewhat Free	Not Free
Overall	237	16.4%	80.2%	3.4%
Karnataka	47	4.3%	89.4%	6.3%
Himachal	48	8.3%	83.3%	8.4%
Rajasthan	48	58.3%	41.7%	0%
Assam	47	0%	97.9%	2.1%
West Bengal	47	10.6%	89.4%	0%

(43%) households reporting the availability of toilets, it is not surprising that the proportion of habitations reported to be ‘fully free’ from open defecation is so small.

10.8 Garbage Collection & Disposal in Habitations

The table alongside presents the analysis of the habitation survey with regard to the existence of any functional mechanism for garbage collection and disposal. As quite expected, there is no such mechanism in most (96%) of the habitations. This is not surprising, especially in the light of the findings that a majority of the households do not have toilets and open defecation is quite common in most of the habitations.

Table-10.11 : Existence of Functional Mechanism for Garbage Collection & Disposal

Category	n	Yes	No
Overall	236	3.8%	96.2%
Karnataka	45	0%	100%
Himachal	48	10.4%	89.6%
Rajasthan	48	2.1%	97.9%
Assam	48	6.3%	93.8%
West Bengal	47	0%	100%

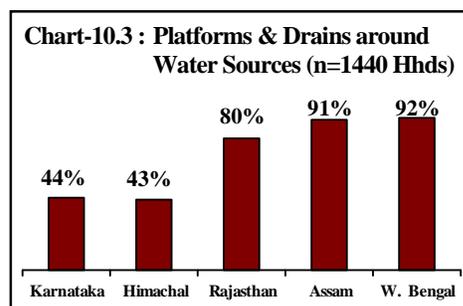

10.9 Cleanliness around the Water Sources

In order to avoid contamination of water, it is highly desirable that proper cleanliness is maintained around the water sources at all times. The analysis of the household survey in this regard is presented in the table alongside. As can be seen, according to most (98%) of the households, the level of cleanliness around the water sources in their areas is good or fair.

Table-10.12 : Cleanliness around the Water Sources

Category	n	Good	Fair	Bad
Overall	1440	45.4%	52.5%	2.1%
Karnataka	288	19.4%	78.8%	1.8%
Himachal	288	83.0%	17.0%	0%
Rajasthan	288	25.4%	68.3%	6.3%
Assam	288	69.0%	30.7%	0.3%
West Bengal	288	30.1%	67.8%	2.1%

When probed about the platform and provision of proper drainage around the water sources, overall, 70% of the households reported in affirmation. Among the 5 states, Assam and West Bengal stand out with over nine-tenth (91% and 92%, respectively) of all the households mentioning that all water sources in their areas have platform and proper drainage.

The findings on the issue of the responsibility of cleaning the water sources in the habitations presented in the table alongside show that overall, in four-fifth (80%) of the habitations, the responsibility lies with the community itself. In the case of Assam and West Bengal, 100% of the habitations have reported that cleaning of the water sources is the sole responsibility of the community. Further, around three-fifth (58%) of the habitations in Rajasthan have mentioned that the responsibility of cleaning lies with the PHED, while two-fifth (40%) of the habitations in Karnataka have mentioned that it is responsibility of Gram Panchayats to clean the area.

Table-10.13 : Responsibility of Cleaning the Water Sources in Habitations

Category	n	PHED	GP	Community
Overall	240	10.7%	10.3%	79.9%
Karnataka	48	0%	40.0%	62.2%
Himachal	48	4.2%	10.4%	87.5%
Rajasthan	48	57.9%	0%	42.1%
Assam	48	0%	0%	100%
West Bengal	48	0%	0%	100%

As regard the frequency of cleaning around the water sources, it was reported as once a month by the habitations where PHED or Gram Panchayat has the cleaning responsibility. In the case of habitations where community was reported to be responsible, the proportion of habitations reporting 'once a month' and 'twice a month' was nearly the same (47% and 53%, respectively). It may be added that almost all the habitations have reported that the community is aware about preventing wastage of water and avoiding water logging in the vicinity of the water sources.

11. Program Benefits/Impact on Rural Population

The impact assessment of the Rajiv Gandhi National Drinking Water Mission (RGNDWM) was made taking into account the following 7 key issues —

1. Increased Availability of Water
2. Increased Functional Water Sources/Reduced Breakdowns
3. Improvement in Environmental Sanitation
4. Reduction in Water Borne Diseases
5. Improvement in Women’s Conditions
6. Utilization of Time Saved
7. Improvement in Overall Health Status

The findings with respect to each of the aforementioned issue are discussed one-by-one ahead.

11.1 Increased Availability of Water

Increased availability and consequently, increased water usage by the rural households have been found to be the biggest program benefits. This is amply evident from the table presented alongside. Overall, an overwhelming majority (96%) of the households have reported increased usage of water.

Table-11.1 : Water Usage at Household

Category	n	Increased	Decreased	Remained Constant
Overall	1439	95.8%	3.5%	0.7%
Karnataka	288	91.3%	7.3%	1.4%
Himachal	288	93.4%	6.3%	0.3%
Rajasthan	287	95.8%	3.9%	0.3%
Assam	288	100%	0%	0%
W. Bengal	288	98.6%	0%	1.4%

11.2 Increased Functional Water Sources/Reduced Breakdowns

When the issue of Program benefits was discussed with the respondents of habitation survey, an overwhelming majority of them (80%) mentioned that the number of water sources in functional condition has significantly increased in the last few years.

Functioning Water Sources (n = 240 Habs.)		
Increased	No Change	Decreased
80.4%	17.1%	2.5%
Break downs (n = 240 Habs.)		
Decreased	Somewhat Decr.	No Change
56.7%	36.1%	7.1%

Further, the respondents in majority (57%) of the habitations also mentioned that there has been a noticeable decrease in the frequency of the supply system breakdowns.

11.3 Improvement in Environmental Sanitation

The household survey findings with regard to improvement in environmental sanitation are presented in the table alongside. As can be seen, overall, three-fourth (74%) of the respondents felt that the Program has had a positive impact in terms of environmental sanitation, the impact being biggest in the State of Himachal Pradesh (95%). Overall, the proportion of habitations reporting positive improvement was found to be more or less same (74%) as that of the respondents of the household survey.

Table-11.2 : Improvement in Environmental Sanitation

Category	n	Yes	No	Don't Know
Overall	1377	73.6%	23.9%	2.5%
Karnataka	287	50.9%	48.4%	0.7%
Himachal	283	95.4%	1.1%	3.5%
Rajasthan	268	85.4%	6.0%	8.6%
Assam	273	75.8%	24.2%	0%
W. Bengal	266	60.5%	39.5%	0%

11.4 Reduction in Water Borne Diseases

Three-fourth (74.5%) of the respondents of the habitation survey also felt that there has been an improvement in the environmental sanitation conditions in their areas due to the increased availability of water. As a result, the incidences of water-borne diseases in the habitation have decreased, as reported by 70% of the respondents, highlighting a positive change in the overall well-being of the community (table alongside).

<i>Environmental Sanitation (n = 240 Habitations)</i>		
Improved	Somewhat Impr.	No Change
23.4%	51.1%	25.5%
<i>Water-Borne Diseases (n = 240 Habitations)</i>		
Decreased	Somewhat Decr.	No Change
69.5%	25.7%	4.8%

11.5 Improvement in Women's Conditions

Access to drinking water has special implications for women and children. The responsibility for fetching water for household needs, sometimes over long distances, is invariably assigned to women or girls. As mentioned under the 'Profile of Respondents' section, over four-fifth (84.6%) of the respondents of the household survey were females. Accordingly, efforts were made to assess the impact of improved access to safe water on women in the villages. The findings are discussed ahead —

Reduced Workload of Women: The women respondents were asked whether or not the ready and increased availability of water has reduced their workload. The analysis is presented in the table alongside. As can be seen, overall, a significant three-fourth (75%) of the respondents have reported in affirmation about reduction in

Table-11.3 : Reduced Workload of Women

Category	n	Yes	No
Overall	1218	75.1%	24.9%
Karnataka	276	52.4%	47.6%
Himachal	195	95.1%	4.2%
Rajasthan	217	89.6%	10.4%
Assam	284	79.1%	20.9%
West Bengal	246	59.8%	40.2%

their workload, the impact being most prominent in Himachal Pradesh, as reported by almost all (95%) the female respondents.

Further, overall, three-fourth (75%) of them have also admitted that due to reduced workload, there has been a significant reduction in fatigue experienced by women. Among the 5 states, the proportion of women reporting this positive impact has been found to be the highest in the State of Himachal Pradesh, as reported by almost all (97%) the female respondents (table alongside).

Table-11.4 : Women Experiencing Reduced Fatigue

Category	n	Yes	No
Overall	1218	75.3%	24.7%
Karnataka	276	52.1%	47.9%
Himachal	195	96.5%	3.5%
Rajasthan	217	89.6%	10.4%
Assam	284	79.1%	20.9%
West Bengal	246	59.8%	40.2%

It has been found that consequent to reduced workload and reduced fatigue, women have now more time to engage themselves in various community activities, as reported by over two-third (71%) of the women respondents of the household survey. Among the 5 states, Himachal Pradesh stands out where almost all women (96%) have mentioned about the increased participation of women in the community activities (table alongside).

Table-11.5 : Increased Women's Participation in Community Activities

Category	n	Yes	No
Overall	1218	70.6%	29.6%
Karnataka	276	46.3%	51.7%
Himachal	195	95.6%	4.4%
Rajasthan	217	75.7%	24.3%
Assam	284	75.6%	24.4%
West Bengal	246	59.8%	40.2%

As regards the Program's impact on children, an overwhelming majority of women (89%) have reported that on account of improved water supply (easier access and adequate availability), children have now more time for studying and playing instead of helping them collect water.

11.6 Utilization of Time Saved

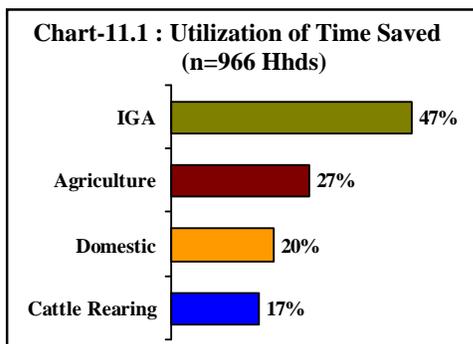

The table alongside presents the findings on various productive activities in which the households are utilizing the time saved on account of improved access to water. As can be seen, people are now able to spend time in more productive activities instead of spending excessive time in collecting water, with a significant amount of 'opportunity cost' associated with it. Among the 5 states, Assam and

Table-11.6 : Utilization of Time Saved in Various Activities

Category	n	Agriculture Production	Cattle Rearing	IGA	Domestic Work
Overall	966	26.7%	16.6%	47.4%	19.5%
Karnataka	166	25.9%	6.6%	54.8%	15.0%
Himachal	270	44.1%	24.5%	41.8%	11.1%
Rajasthan	223	41.7%	37.7%	7.6%	33.6%
Assam	170	0.7%	0%	77.0%	19.4%
W. Bengal	137	1.4%	0%	78.7%	19.2%

West Bengal stand out where around four-fifth (77% and 79%, respectively) of the households have reported that they are utilizing the time saved for income generating activities. The savings of time in collecting water has also helped people in Himachal Pradesh and Rajasthan to focus more on agriculture production, as reported by over two-fifth of the households (44% and 42%, respectively) in these states.

Overall, 5 states combined, around a significant half (47%) of the households are reportedly utilizing the time saved for income generating activities, while over one-fourth (27%) of the households are utilizing the time saved on agriculture. People are now able to focus more even on domestic works and cattle rearing, as reported by a significant proportion of the households (20% and 17%, respectively), as shown in the chart alongside.

“Because of this scheme, many good things have happened in lives of people in the community. Earlier, people used to carrying water from far off places; now it is easily available. Women....., there is saving in their time which they are using for domestic work, agriculture or in taking rest.”

FGD Participants, Dist. Kullu, Block-Kullu, Himachal Pradesh

“People are now getting water easily and nearby. So, women do not have to work very hard now. They need to spend less time in collecting water. The time saved is used by them for domestic work. Many of them use this time for income generating activities also.”

FGD Participants, Dist. Shimoga, Block-Shikaripura, Karnataka

“Earlier people used to bring water from a distance of 5 kms. Since the construction of GLR in the village, people do not have to go for very far. Because of this, people do not get tired and they have saved time also, which they can use for agriculture purpose.”

FGD Participants, Dist. Barmer, Block-Sindari, Rajasthan

“Since water is available near the houses, people are able to save lot of time, which they can use for domestic and other works.”

FGD Participants, Dist. Kamroop, Block-Sowalkuchi, Assam

“Water is now available close to outsource and because of this people are getting spare time for attending domestic works and income generating activities.”

FGD Participants, Dist. Hawrah, Block-Shyampur-1, West Bengal

11.7 Improvement in Overall Health Status

One would expect that improved access to safe drinking water would result in the improvement of overall health status of the community. However, the household survey findings presented in the table alongside are contrary to this expectation. According to most of the

Table-11.7 : Improvement in Overall Health Status of the Family

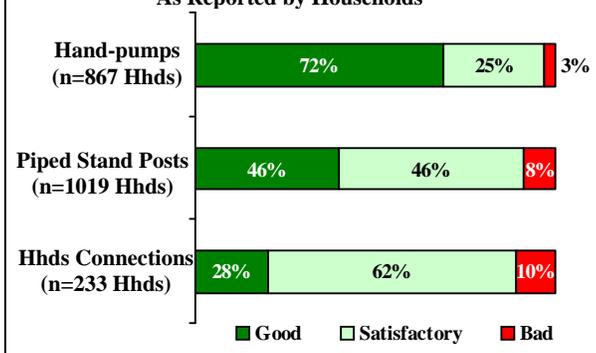

Category	n	Yes	No	No Change
Overall	1416	4.1%	0.6%	95.3%
Karnataka	280	2.1%	0%	97.9%
Himachal	288	1.0%	0%	99.0%
Rajasthan	287	6.6%	2.8%	90.6%
Assam	279	5.0%	0%	95.0%
West Bengal	282	5.7%	0%	94.3%

households (95%), there is no perceptible change in the overall health status of their families. The general sentiment was ‘We were O.K. before also, and we are O.K. now’. Only a paltry 4% have reported a positive impact on the overall health of their families. Most of these households have mentioned that now they are not required as frequently to spend time & money in traveling to health facilities and they are also able to save money that was otherwise spent on medicines and doctor’s fee. It may be mentioned that the findings are more or less similar for both the ‘most affected’ as well as the ‘least affected’ districts.

11.8 Overall Performance of Water Sources

In order to assess the overall performance of the various water sources, as perceived by the beneficiaries, they were asked to rate it as ‘good’, ‘satisfactory’ or ‘bad’. The analysis is presented in the following table. As can be seen, almost all the households (97%) have rated the performance of hand-pumps as good or satisfactory, while more or less a similar proportion

Chart-11.2 : Overall Performance of Water Sources — As Reported by Households

(92%) of household felt that the performance of piped stand post was good or satisfactory. Even in the case of household connections, 9 out of 10 households have rated it as good or satisfactory.

12. Sustainability

Sustainability of drinking water sources and schemes is a process which facilitates the existing/new drinking water supply projects to provide safe drinking water in adequate quantity, even during distress periods, duly addressing equity, gender, vulnerability, convenience and consumer preference issues, through conjunctive use of groundwater, surface water and roof-water harvesting, exclusive to rural drinking water schemes. The main aim of providing sustainability of drinking water schemes is that such schemes will not slip back from universal access of safe drinking water to the community throughout the design period of schemes.

The paradigm shift in the new framework of RGNDWM, Department of Drinking Water Supply (2009-12) is to move towards achieving universal access to rural population for having safe and sustainable drinking water supply rather than a mere coverage of habitations, the latter not necessarily speaking about equity and vulnerability issues. Therefore the aim is to work at achieving household level drinking water security, which shall obviously ensure universal access. Adoption of appropriate technology, revival of traditional systems, conjunctive use of surface and ground water, conservation, rain water harvesting and recharging of drinking water sources have been given major emphasis in the new approach.

Under the new framework, the four elements of sustainability are — (a) *Source Sustainability*: ensuring availability of safe drinking water in adequate quantity throughout the year; (b) *System Sustainability*: optimizing the cost of production of water, devising proper protocol for O&M, capacity building of PRIs and awareness generation; (c) *Financial Sustainability*: proper utilization of Twelfth Finance Commission (TFC) and O&M funds under Revised RWSP guidelines and recovering at least 50% cost through flexible methods devised by the local self government and improving energy efficiency; and (d) *Social and environmental Sustainability*: proper project management and involvement of all key stakeholders.

One of the prime objectives of the study was to assess the sustainability of water sources in the habitations. In order to calculate the *Sustainability Index*, a total of 29 parameters under 5 broad aspects, namely, *technology aspects*, *community and social aspects*, *financial aspects*, *water quality aspects* and *training aspects* were identified as detailed in the following table.

Technology Aspect

30. Functionality of Source
31. No. of functional points increased
32. Year round functionality of source
33. Break down frequency
34. Time taken for repairs
35. Availability of equipment/space
36. Technical skills of community

Community & Social Aspect

37. Ownership of water sources
38. Choice of technology
39. Access to all groups
40. Usage of sources
41. O&M measures taken
42. Community willingness to take O&M
43. Care of sources by women
44. Satisfaction with water services

Financial Aspect

45. Community contribution
46. Availability of funds
47. Entity setting-up water tariff charges
48. Affordability of water charges
49. Whether community consulted in tariff-setting
50. Flexibility in user payment
51. Provision of subsidized tariff for poor (SC/ST)

Water Quality Aspect

52. Acceptability of quality
53. No. of sources with acceptable quality
54. Access to safe water
55. Source reliability

Training Aspect

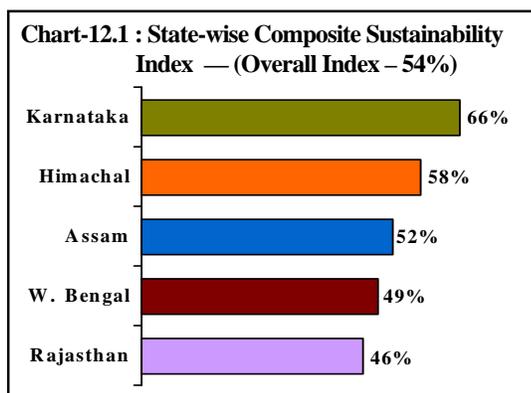

56. Category of personnel trained
57. Gender-wise training
58. Preference for women in training of hand-pumps repair

For each of the aforementioned 29 parameters, the responses from the households were quantified on a scale of 1 to 4 and State-wise averages were computed for each of them. This allowed us to identify the critical sustainability parameters that were relatively strong or weak in each of the sample states. The values of sustainability index and its significance is given in the table alongside.

Sustainability Index	
Value	Significance
76%-100%	Highly Satisfactory
51%-75	Satisfactory
26%-50%	Poor
0%-25%	Very Poor

12.1 Composite Sustainability Index

The State-wise findings on the composite (all 5 broad heads combined) sustainability index are presented in the chart alongside. As can be seen, the overall (all 5 states and all 5 broad aspects combined) sustainability index works out to 54%, which is only marginally above the range of 'Poor'. The overall sustainability of water sources in the states of West Bengal and

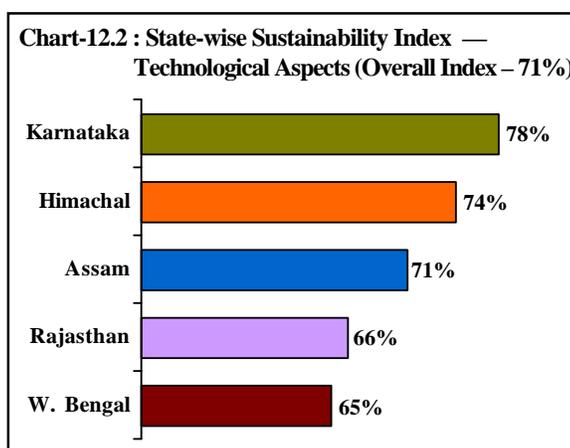

Rajasthan is found to be poor, while the performance of Himachal Pradesh, Assam and Karnataka is found to be satisfactory. Among the five states, Karnataka is found to be the best performing State with a composite sustainability index of 66%.

As already mentioned, we have also worked out sustainability index for each State in respect of each of the 5 major aspects, that is, technology aspects, community & social aspects, financial aspects, water quality aspects and training aspects. The findings are presented on each aspects one-by-one hereunder —

Technological Aspects

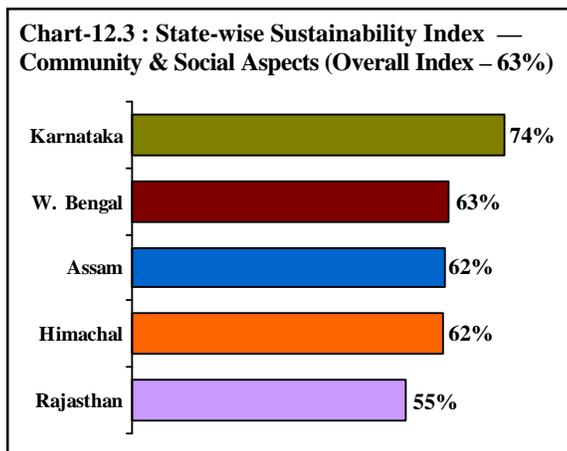

The overall (all 5 states combined) sustainability index in respect of the technology issues is found to be 71%, which is satisfactory. Among the 5 states, Karnataka stands out with a composite index of 78%, as shown in the chart alongside. This indicates that in terms of technological aspects, sustainability of water sources in this State is highly satisfactory.

In other words, in the State of Karnataka, water sources were functional or partially functional throughout most part of the year and number of functional water points had increased. There were no or only few breakdowns and in these cases, the repairs were done quickly. Further, the equipment and spare parts were easily available for nearly all types of repairs. Besides, community was also aware of the technical skills required for repairs of water supply system.

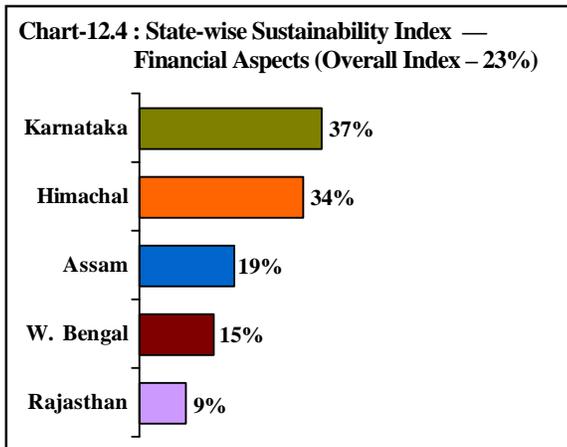

Community & Social Aspects

The State-wise sustainability index in respect of community and social aspects presented in the chart alongside shows that the overall (all 5 states combined) index is 63%, which is satisfactory. Performance of all the 5 states is found to be satisfactory, with Rajasthan scoring lowest (55%) and Karnataka scoring the highest (74%).

Financial Aspects

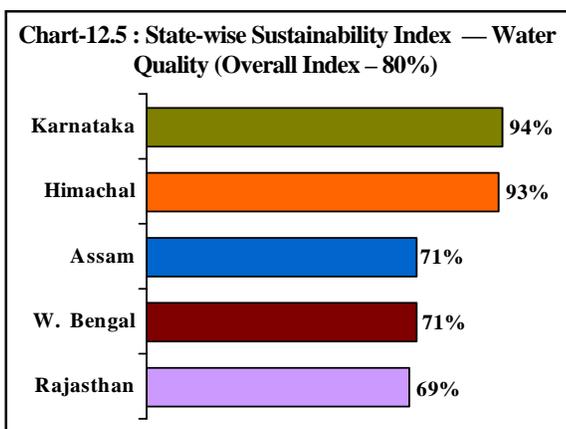

The State-wise findings on sustainability index with respect to financial aspects presented in the chart alongside shows that overall (all 5 states combined) situation is very poor (23%). Among the 5 states, Rajasthan is found to be the worst performing State with the sustainability index of only 9%. Even in the case of Karnataka, that had fared very well in terms of technological and community &

social aspects, the sustainability index on financial aspects is found to be poor.

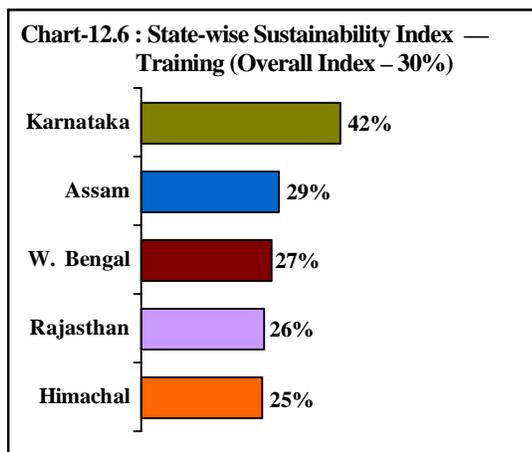

Water Quality Aspects

In terms of water quality, the sustainability index of Karnataka and Himachal Pradesh is found to be highly satisfactory (94% and 93%, respectively), as shown in the chart alongside. Even the other 3 states (Assam, West Bengal and Rajasthan) have fared satisfactorily in this regard. The overall (all 5 states combined) sustainability index is also found to be 80%, indicating that the level of satisfaction in the community with regard to quality and reliability of drinking water is very high.

Training Aspects

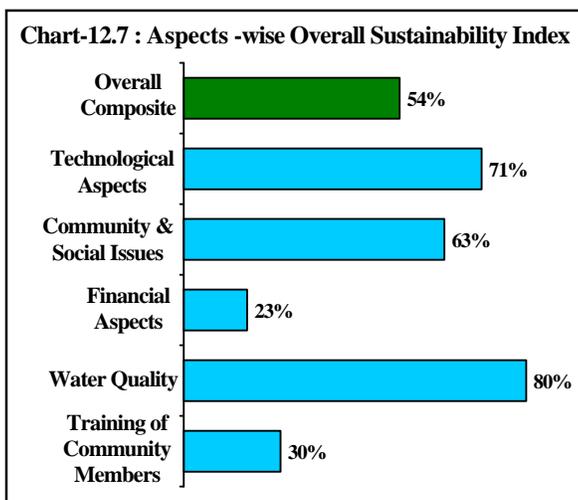

The findings on sustainability index with regard to the training of community members are presented in the chart alongside. The overall situation (all 5 states combined) presents a poor picture with a sustainability index of only 30%. The State of Himachal Pradesh has fared very poorly with a sustainability index of only 25%, while the other 4 states have fared poorly, with the sustainability index ranging between 26% and 42%.

Since women are the principal beneficiaries of the Mission and are pivot around which sustainability is evolved, it is of critical importance that women are involved at all the stages of planning, implementation and management of rural water supply schemes. Women's associations could provide a strong framework for community participation. However, the aforementioned findings make it amply evident that provision of training to the community, especially the women has not been given adequate and much needed attention by any of the five sample states.

12.2 Aspects-wise Overall Sustainability Index

The findings on the overall (all 5 states combined) sustainability index with respect to each of the five broad aspects are presented in the chart alongside. As can be seen, the sustainability indices with respect to ‘financial aspects’ and ‘training of community members’ are only 23% (very poor) and 30% (poor), respectively. The poor performance of the states on these two major aspects has had an adverse impact on the overall composite sustainability

index and it has barely managed to be in the ‘satisfactory range’ (54%), despite the fact that the sustainability indices on the other three major aspects — ‘technological aspects’, ‘financial aspects’ and ‘water quality’ are in either ‘satisfactory’ or ‘highly satisfactory’ range (71%, 63% and 80%, respectively).

A comparison of overall sustainability index with respect to each of the 5 broad aspects for ‘most affected’ and ‘least affected’ sample districts is presented in the table alongside. As can be seen, only in the case of ‘water quality’, there is a noticeable variations between the sustainability index of ‘most affected’ and ‘least affected’ districts (76% and 84%, respectively). As regards the other four broad aspects, the values of sustainability indices are quite comparable.

Broad Aspects	Sustainability Index	
	Most Affected	Least Affected
Technology Issues	70.4%	70.7%
Community & Social Issues	62.2%	64.0%
Financial Aspects	23.4%	22.5%
Water Quality	75.6%	84.0%
Training of Community Members	29.7%	29.4%

12.3 Rain Water Harvesting Structure

In view of fast growing population, urbanization and industrialization on one side and diminishing water resources on the other, it has become imperative to conserve available water and harvest rain water to the maximum extent possible. Storage of rain water for drinking water both at the community level and at the household level will ensure drinking water security even in adverse conditions for few months. With sufficient storage capacity it may be sufficient for the whole year.

In the context of the aforementioned, the *Pradhans* of the sample Gram Panchayats were asked if they had installed any rain water harvesting structure in their respective Gram Panchayat. The findings presented in the table alongside show that installation of rain water harvesting structure is reported only in less than two-fifth (36%) of the sample GPs. Surprisingly, none of the GPs in West Bengal and Assam have reported about installing such structures.

Table-12.1 : GPs Reporting Rain Water Harvesting Structure

Category	n	Yes	No
Overall	62	22 (35.5%)	40 (64.5%)
Karnataka	11	8	3
Himachal	12	4	8
Rajasthan	13	10	3
West Bengal	12	0	12
Assam	14	0	14

Further analysis has revealed that the number of GPs reporting rain water harvesting structures in ‘most affected’ is twice than that of those in the ‘least affected’ districts (15 GPs as against 7 GPs). This is owing to the fact that water is generally available at a shallow depth in the ‘least affected’ districts and as such, in terms of water endowments, the ‘least affected’ districts are much better off than the ‘most affected’ ones.

Information regarding installation of rain water harvesting structure was also collected during the habitation survey. The findings presented in the table alongside show that the proportion of habitations responding in affirmation is still smaller (15%) as compared to that of the GPs. Once again, none of the habitations in West Bengal and Assam has reported existence of any such structure. As quite expected, the proportion of habitations reporting rain water harvesting structures is found to be the highest (48%) in the State of Rajasthan. The details of water harvesting structures as reported by the habitations are presented in the following table —

Table-12.2 : Habitations Reporting Rain Water Harvesting Structure

Category	n	Yes	No
Overall	240	15.0%	85.0%
Karnataka	48	18.7%	81.3%
Himachal	48	8.3%	91.7%
Rajasthan	48	47.9%	52.1%
West Bengal	48	0%	100%
Assam	48	0%	100%

Details of Water Harvesting Structures as Reported by Habitations	
☛ Water harvesting tank constructed in 2007	7 Habitations (Karnataka-7)
☛ Water harvesting tank constructed under Agriculture Development Scheme	1 Habitations (Karnataka-1)
☛ Water harvesting tank constructed by GP	5 Habitations (Himachal Pradesh-4, Rajasthan-1)
☛ Water harvesting tank constructed under NREGS	19 Habitations (Rajasthan-19)
☛ Water harvesting tank constructed by individuals	12 Habitations (Rajasthan-12)

13. Major Findings

13.1 Status of Fully Covered Habitations

Based on the information received from the State officials, between the period 2003 and 2009, there has been significant increase in the proportion of fully covered (FC) habitations in all the 5 states. Among the 5 states, Rajasthan and Assam stand out with the highest increase (62 and 51 percentage points). As per the official records, the present status of the fully covered habitations in the 5 study states is in the range of 75% (Himachal Pradesh) to 95% (Rajasthan).

13.2 Access to Safe Drinking Water

There has been a tremendous improvement in the rural populations' access to safe drinking water sources between the pre-2003 and the present period across all the 5 states. The improvement was phenomenal in the case of Rajasthan where currently, over nine-tenth (91%) of the rural households have access to safe drinking water as compared to less than one-tenth (9%) of them prior to 2003. During the same period, Himachal Pradesh has also registered an equally impressive improvement; currently all the households (100%) have access to safe drinking water as compared to less than three-fifth (56%) prior to 2003. Overall, 5 states combined, over nine-tenth (93%) of the rural population at present has access to safe drinking water sources; the improvement of 32 percentage points is a reflection of the commendable progress made under the Mission.

Prior to 2003, compared to the households (71%) of the 'least affected' districts, a much smaller proportion of the households (50%) in 'most affected' districts had access to safe drinking water. With the advent of the Mission, the situation in the 'most affected' areas has improved to a point where the proportions of the households in least and 'most affected' areas having access to safe drinking water are quite comparable (92% and 95%, respectively).

Parameters of Access to Drinking Water

In order to assess the issue of access to drinking water in a holistic manner, efforts were made to elicit information from the respondents of the household survey on the following 5 key parameters.

- Safe and Round-the-year Availability
- Safe, Round-the-Year and Sufficiency
- Distance of Water Source

- Time Spent in Collecting Water
- Social Inclusion

It may be highlighted that the first 3 are the defining parameters of the ‘fully covered’ status of a habitation. Accordingly, these are discussed first.

Safe and Round-the-year Availability : Overall, around two-third (66%) of the households having access to safe drinking water sources are getting round-the-year supply of drinking water. Among the 5 states, Assam stands out as the best performing State with nearly four-fifth (76%) of the households receiving round-the-year supply of water from safe sources. On the other hand, West Bengal is found to be the worst performing, where two-fifth (42%) of the households have reported that they are deprived of this facility.

Safe, Round-the-Year and Sufficiency : Overall, only three-fifth (63%) of the households has reported to be receiving sufficient quantity of water from safe sources on round-the-year basis. Among the 5 states, Assam stands out as the best performing State where this was reported by three-fourth (76%) of the households. On the other hand, Karnataka was found to be the worst performing State where close to half the households (46%) have reported that they were not receiving round-the-year supply of sufficient quantity of water from safe sources.

A comparative analysis of households reporting safe, safe & round-the-year and safe, round-the-year and sufficient supply of drinking water shows that although, the proportion of households having access to safe water is quite high (ranging from 85% to 100%), the proportion of households reporting safe, round-the-year and sufficient water supply is much smaller (54% to 76%). The difference was found to be as high as 43 percentage points in the case of West Bengal.

Distance of Water Source

Overall, all 5 states combined, almost all the households having access to safe drinking water have reported that the main source of water was located within 1.6 kms. from their homes. As regards Himachal Pradesh (hilly State), all the households surveyed have reported that the main safe source of water was located within 1.6 km or within 100 m elevation difference. Thus, it can be safely concluded that the proportion of ‘fully covered’ habitations across the 5 study states are in the range of 54% to 76%.

It may be highlighted that there are significant differentials between the ‘fully covered’ status based on the State-level data and the findings of the household survey. The difference is quite prominent in the State of Karnataka, Rajasthan and West Bengal (39, 29, and 28 percentage points, respectively).

Time Spent in Collecting Water

Overall, the average daily time spent by the households in collecting drinking water (from safe sources) is 52 minutes. Considering the numerous constraints in the rural areas (frequent power cuts for long hours and low voltage, low water pressure, lack of proper maintenance of equipment, less than adequate number of sources, etc.), the average time of 52 minutes per day spent by the households is not much and the situation can be considered as quite satisfactory.

Social Inclusion

It is indeed heartening to note that almost all the households across the 5 study states have reported that there is no discrimination whatsoever, with regard to access to drinking water sources.

Moving towards Tapped Water Supply

Compared to their status prior to 2003 and present (2009), the proportion of households having access to tap water has improved quite significantly in all the 5 states. Overall, it has increased from 24% to 71%. During the same period, the proportion of households dependent on hand-pump/tube-bore wells has gone down, except in the State of Rajasthan, where prior to 2003, 80% in Barmer district (most affected) and 84% households in Dholpur district (least affected) were receiving drinking water from open wells. Currently, the situation has changed to a point where only 8% households in Barmer and 6% households in Dholpur are using open well water, while the majority has now access to hand-pump or tap water provided under the Mission.

There has been a drastic change, especially in the case of Rajasthan, Assam and West Bengal where prior to 2003, the proportion of the households having access to piped water supply was next to nothing (1%, 2% and 7%, respectively). Currently, these states have registered a significant improvement, with a substantial increase in the proportion of households having access to piped water supply (35, 53 and 82 percentage points). Among the 5 states, Himachal Pradesh and Karnataka stand out where the proportion of households having access to piped water supply stands at 100% and 84%, respectively.

Alternate Sources of Drinking Water

As already discussed, only 63% households have access to safe, round-the-year and sufficient quantity of water, implying that a significant 37% do not have this facility. These are the households that have to depend on alternate sources of drinking water. It has been found that overall, the alternate sources for 70% of such households are safe. State-wise, most of the households (82% to 92%) in the states of Karnataka, Assam and West Bengal have reported that their alternate sources of water are safe. Whereas, in the case of

Rajasthan, the alternate sources of water was unsafe ('open wells' and 'taanka'), as reported by a significant two-fifth (41%) of the households.

Further, it was found that despite the alternate sources located within the statutory distance of 1.6 kms from their homes for almost all the households (97%), average time spent per trip in collecting water is reported to be nearly three times as compared to that of the main source (144 minutes for alternate & 52 minutes for main sources).

13.3 Water Quality

Satisfaction with the Water Quality

It is encouraging to note that overall, an overwhelming majority of the households (93%) have reported to be satisfied with the water quality. Among the 5 states, water quality is a major issue only in the State of Rajasthan, as reported by half the households (50%) surveyed in the State.

Almost all these households belong to the 'most affected' district of Barmer. It may be highlighted that overall, around four-fifth (78%) of the households in the 5 'most affected' districts have reported that the water quality of their main sources was satisfactory. With 90% households in the 'least affected' districts satisfied with the water quality of the main sources, there is not much difference between the 'least affected' and 'most affected' districts in terms of water quality as perceived by the households. As for the alternate sources, overall, 71% of the households have expressed satisfaction about its water quality. Among the 5 states, water quality of the alternate sources is found to be a major issue in the states of Rajasthan and Assam, where majority of the respondents (56% and 51%, respectively) have reported dissatisfaction.

Provision of Water Testing Kits to Gram Panchayats

It is disheartening to note that out of the 63 sample Gram Panchayats, only 18 have reported about being provided with the field-testing kit. Surprisingly, none of the 14 sample Gram Panchayats of West Bengal and only 1 Gram Panchayat in Assam has reported affirmatively in this regard. Ironically, the proportion of GPs provided with the field testing kits is much smaller for the 'most affected' districts as compared to the 'least affected' ones (23% vs 33%).

Testing of Water Sources by Technical Person

It is also disheartening to note that overall, the respondents of four-fifth (79%) of the sample habitations have reported in negative about the testing of water sources. Further analysis has revealed that even in the case of 'most affected' districts, water sources have not been tested in three-fourth (76%) of the 120 habitations. As a matter of fact, only 5% of all the sample

habitations have reported about Gram Panchayats making any effort with regard to maintaining water quality of sources.

Trainings on Water Quality Monitoring and Surveillance

The *Pradhans* of only 23 out of the 63 sample GPs affirmed about the provision of training to grassroot workers. According to them, training was provided on quality, monitoring and sanitation & hygiene issues. Among the 5 states, Karnataka stands out with all the 12 sample GPs reporting the provision of training to grassroot workers. Gender-wise, it emerged that in a large majority of the Gram Panchayats (50 out of 63), no woman has received any training. Among the 5 states, Karnataka stands out where 7 out of the 12 sample GPs have mentioned about women having received training. Considering that the responsibility of collecting water lies mainly with the females of the households, the overall situation is not encouraging.

13.4 Operation & Maintenance

Functional Water Sources

Over two-third (70%) of the hand-pumps and overwhelming majority (91%) of the tapped water supply sources were functional as reported by the respondents of the habitations survey. According to around a significant one-fifth (18%) of them, the hand-pumps had become defunct mainly due to ground water depletion. This problem was found to be pronounced mainly in the states of Karnataka and Rajasthan, as reported by a significant proportion of habitations (54% and 25%, respectively). The other major reason for the defunct hand-pumps was cited as lack of proper maintenance, as reported by the respondents of 16% habitations.

As regards the piped water supply, one-third (35%) of the habitations have reported no breakdowns in the past one year, while around half (49%) have reported the frequency of breakdowns as 2-3 times in the past one year. The breakdown frequency of more than 3 times in the past one year was reported by only 8% of them. In the context of the rural settings and other constraints, the overall situation can be said to be satisfactory.

Responsibility of O&M

Overall, only a small proportion (5%) of the households was of the view that O&M should be the responsibility of the community. Among the 5 states, Himachal Pradesh stands out with the proportion of such households being the highest (12%). *When probed about the existence of any committee in their village/habitation that is responsible for maintenance of water sources, almost all the households (99%) responded in negative.*

The proportion of households willing to pay for the operation & maintenance of the water supply system was found to be very small (8%). Among the 5 states, Himachal Pradesh

stands out with one-fourth (25%) of the households willing to pay for O&M. According to the *Pradhans* of over half (56%) of the sample GPs, prevailing poverty among the community was the main reason for their unwillingness. Further, 26% of them were of the view that the communities would be able to pay some amount (Rs. 10/- to Rs. 50/- per month) towards O&M, while around one-fifth (18%) of them mentioned that the community in their areas considered O&M as the responsibility of the GPs.

Role of GPs in O&M of Water Supply System

Over half of the Gram Panchayats have expressed their inability to take the responsibility of O&M. Among the 5 states that have reported to be capable, Karnataka stands out where *Pradhans* of all the sample Gram Panchayats have stated that they are capable to take this responsibility. As regards the formal handing over of O&M of the assets created under the Mission, a large majority of the Gram Panchayats (50 out of 63) have responded in negative. Among the 5 states, Karnataka stands out where O&M has been formally handed over to all the 12 sample GPs. It emerged that in 70% of the GPs, PHED has the responsibility of O&M, while in 25% of the cases, the responsibility is reported to be with the GPs (mostly in Karnataka and some in West Bengal). As regards the remaining 3 GPs, the O&M responsibility lies with the VLWSC.

13.5 Water Tariff

As per the household survey, 14.6% (total 210) of all the households were found to be having tap connections. Close to nine-tenth (87%) of these households have reported to be paying water charges on a regular basis. It may be mentioned that in Rajasthan, none of the sample households have reported to be having tap connection. Among the other 4 states, Himachal Pradesh stands out where all the households are reportedly paying water charges regularly. According to the *Pradhans* of two-third (19 out of 30) such GPs, over four-fifth (83%) of all the households were paying water tariff on a regular basis. Almost all (95%) the households have expressed satisfaction with regard to the water charges paid by them vis-a-vis the quantity/quality of water supply received by them.

The average amount of monthly water charges per household is found to be lowest (Rs. 12.70/- in Himachal Pradesh and highest (Rs. 53.80/-) in Assam. Overall, 4 states combined, the average monthly water charges per household works out to Rs. 22.30/. No variations were found in the water charges among the households belonging to the different social categories (general, scheduled caste or scheduled tribe). Further, an overwhelming majority (88%) of the households having tap connections had paid installation charges. This was lowest (Rs. 526.60/- per household) in Himachal Pradesh and highest (Rs. 1840.00/- per month per household) in West Bengal. Overall, 4 states combined, the average installation charges per household works out to Rs. 644.30/-.

It may be highlighted that the user charges for Public Stand Post (PSP) were collected only in the State of Karnataka, as reported by the village Pradhans of the 12 sample Gram Panchayats. According to them, the average monthly amount of water charges per household was Rs. 10/- for all sections of the society.

According to the village *Pradhans*, in most of the GPs, PHED was responsible for setting-up water tariff. Whereas, wherever the supply system had been formally handed-over to the GPs, it was PRIs' responsibility. In these cases, water tariff was set-up in accordance with the Government Order. As regards informing the community about the water tariff, the village *Pradhans* mentioned about the use of public announcement, public display or through 'Watermen' for the purpose. On the issue of community being consulted before setting-up the water tariff, village *Pradhans* of only a few GPs responded in affirmation. According to most of them, around 50% of the O&M cost is recovered from the user charges.

13.6 Community Participation/Existence of VWSC

It is disheartening to note that less than 1% of the households mentioned about the existence of village water and sanitation committee (VWSC) in their areas. When discussed with the *Pradhans*, it emerged that VWSCs were existing in only one-fifth (13 out of 63) of the sample Gram Panchayats. Among the 5 states, Karnataka stands out where the presence of VWSC was reported by half the sample Gram Panchayats. While VWSC meetings were reportedly conducted only in 9 out of the 13 GPs, participation of women and scheduled caste community members in the VWSC meetings was reported in only 7 out of the 13 GPs. Further, in only 6 out of the 13 GPs, all VWSC members have reportedly received training.

13.7 Knowledge, Practice and IEC on Hygiene & Sanitation

During the study, Gram Panchayats, habitations and households were probed about any campaign organized in their area on water & sanitation and hygiene. Interestingly, there are significant variations among the proportion of GPs, habitations and households responding in affirmation about the campaign on water & sanitation and hygiene (71%, 24% and 13%, respectively). This is probably an indication that some campaigns were organized at Gram Panchayat level, but this has not percolated to the grassroot-level, that is, the household level where information/awareness is needed the most. At the household level, barring Himachal Pradesh, the situation in the other 4 states is pathetic, with their proportion responding in affirmation about campaign ranging between 0% and 8%.

At the habitation level, less than one-fourth (24%) of them reported about any awareness campaign organized in their area. Most of these habitations mentioned about total sanitation campaign (TSC), while a few of them mentioned about Jal Rath Yatra/Jal Chetna Abhiyan (in Rajasthan) and campaign by Health Deptt. on water, sanitation & pollution free environment. Use of interpersonal communication (IPC) for awareness generation was

reported by only an abysmally small proportion of households 7%. In the near absence of IEC activities, it is no surprise that open defecation is so widely prevalent in most (80%) of the sample habitations. Besides, there is no functional mechanism for garbage collection, as reported by almost all the sample habitation (96%).

Main source of information on personal & household hygiene was found to be radio or TV, as reported by an overwhelming majority (88%) of the households. During the habitation survey, when probed on the issue of training of VWSC members or teachers on hygiene education, almost all the habitations have responded in negative. Since in most cases VWSCs are not formed, these findings are not surprising.

13.8 Program Benefits/Impact on Rural Population

Increased Availability of Water

Increased availability and consequently, increased water usage by the rural households have been found to be the biggest program benefits. Overall, an overwhelming majority (96%) of the households have reported increased usage of water.

Increased Functional Water Sources/Reduced Breakdowns

When the issue of Program benefits was discussed with the respondents of habitation survey, an overwhelming majority of them (80%) mentioned that the number of water sources in functional condition has significantly increased in the last few years. Further, the respondents in majority (57%) of the habitations also mentioned that there has been a noticeable decrease in the frequency of the supply system breakdowns.

Improved Environmental Sanitation & Reduction in Water Borne Diseases

Overall, three-fourth (74%) of the household survey respondents felt that the Program has had a positive impact in terms of environmental sanitation. This was most prominent in the State of Himachal Pradesh (95%). Further, three-fourth (74.5%) of the habitation survey respondents have also reported an improvement in the environmental sanitation in their areas due to the increased availability of water. As a result, the incidences of water-borne diseases in the habitation have decreased, as reported by 70% of the respondents, highlighting a positive change in the overall well-being of the community.

Improvement in Women's Conditions

Overall, a significant three-fourth (75%) of the respondents have reported in affirmation about reduction in their workload, the impact being the most prominent in Himachal Pradesh, as reported by almost all (95%) the female respondents. Three-fourth (75%) of them have also admitted that due to reduced workload, there has been a significant reduction in fatigue experienced by women. Among the 5 states, the proportion of women reporting

this positive impact has been found to be the highest in the State of Himachal Pradesh, as reported by almost all (97%) the female respondents.

Consequent to reduced workload and reduced fatigue, women have now more time to engage themselves in various community activities, as reported by over two-third (71%) of the women respondents of the household survey. Among the 5 states, Himachal Pradesh stands out where almost all women (96%) have mentioned about the increased participation of women in the community activities. As regards the Program's impact on children, an overwhelming majority of women (89%) have reported that on account of improved water supply (easier access and adequate availability), children have now more time for studying and playing, instead of helping them collect water.

Utilization of Time Saved

People are now able to spend time in more productive activities instead of spending excessive time in collecting water, with a significant amount of 'opportunity cost' associated with it. Among the 5 states, Assam and West Bengal stand out where around four-fifth (77% and 79%, respectively) of the households have reported that they are utilizing the time saved for income generating activities. The savings of time in collecting water has also helped people in Himachal Pradesh and Rajasthan to focus more on agriculture production, as reported by over two-fifth of the households (44% and 42%, respectively) in these states. Overall, 5 states combined, around a significant half (47%) of the households are reportedly utilizing the time saved for income generating activities, while over one-fourth (27%) of the households are utilizing the time saved on agriculture. People are now able to focus more on domestic works (20%) and cattle rearing (17%).

Improvement in Overall Health Status

According to most of the households (95%), there is no perceptible change in the overall health status of their families. The general sentiment was 'We were O.K. before also, and we are O.K. now'. Only a paltry 4% have reported a positive impact on the overall health of their families. Most of these households mentioned that now they do not have to spend time & money as frequently in seeking treatment for water borne diseases.

Overall Performance of Water Sources

In order to assess the overall performance of the various water sources, as perceived by the beneficiaries, they were asked to rate it as 'good', 'satisfactory' or 'bad'. The study has revealed that almost all the households (97%) have rated the performance of hand-pumps as good or satisfactory, while more or less a similar proportion (92%) of household felt that the performance of piped stand post was good or satisfactory. Even in the case of household connections, 9 out of 10 households have rated it as good or satisfactory.

13.9 Sustainability

One of the prime objectives of the study was to assess the sustainability of water sources in the habitations. In order to calculate the *Sustainability Index*, a total of 29 parameters under 5 broad aspects, namely, *technology aspects*, *community and social aspects*, *financial aspects*, *water quality aspects* and *training aspects* were identified. For each of these 29 parameters, the responses from the households were quantified on a scale of 1 to 4 and State-wise averages were computed for each of them. Sustainability index of 76%-100% was considered highly satisfactory, 51%-75 considered as satisfactory, 26%-50% considered as poor and 0%-25% was considered as very poor.

Composite Sustainability Index : Overall (all 5 states and all 5 broad aspects combined) sustainability index works out to 54%, which is only marginally above the range of 'Poor'. The overall sustainability of water sources in the states of West Bengal and Rajasthan is found to be poor (49% & 46%, respectively), while the performance of Himachal Pradesh, Assam and Karnataka is found to be satisfactory (58%, 52% and 66%, respectively).

Technological Aspects : The overall (all 5 states combined) sustainability index in respect of the technology issues is found to be 71%, which is satisfactory. While it is highly satisfactory for Karnataka (78%), it is satisfactory in case of the other 4 states (65% to 74%).

Community & Social Aspects : Overall (all 5 states combined) sustainability index is found to be 63%, which is satisfactory. Performance of all the 5 states is found to be satisfactory, with Rajasthan scoring lowest (55%) and Karnataka scoring the highest (74%).

Financial Aspects : Findings on sustainability index with respect to financial aspects shows that overall situation is very poor (23%). State-wise, the performance of Rajasthan, West Bengal and Assam is found to be very poor (9%, 15% and 19%, respectively), while the performance of Himachal Pradesh and Karnataka was found to be poor (34% and 37%, respectively).

Water Quality Aspects : In terms of water quality, the sustainability index of Karnataka and Himachal Pradesh is found to be highly satisfactory (94% and 93%, respectively), while the other 3 states have fared satisfactorily in this regard (69% to 71%). The overall (all 5 states combined) sustainability index is also found to be highly satisfactory (80%), indicating that the level of satisfaction in the community with regard to quality and reliability of drinking water is very high.

Training Aspects : The overall situation (all 5 states combined) presents a poor picture with a sustainability index of only 30%. The State of Himachal Pradesh has fared very poorly with a sustainability index of only 25%, while the other 4 states have fared poorly, with the sustainability index ranging between 26% and 42%. The aforementioned findings make it

amply evident that provision of training to community members, especially the women has not been given adequate and much needed attention by any of the five sample states.

Evidently, the poor performance of the states with respect to ‘financial aspects’ and ‘training of community members’ has had an adverse impact on the overall composite sustainability index and it has barely managed to be in the ‘satisfactory range’ (54%). This is despite the fact that the sustainability indices on the other three major aspects — ‘technological aspects’, ‘financial aspects’ and ‘water quality’ are in either ‘satisfactory’ or ‘highly satisfactory’ range (71%, 63% and 80%, respectively).

A comparison of overall sustainability index with respect to each of the 5 broad aspects for ‘most affected’ and ‘least affected’ sample districts shows any noticeable variations only in the case of ‘water quality’ aspect (76% and 84%, respectively). As regards the other four broad aspects, the values of sustainability indices are quite comparable.

Installation of Rain Water Harvesting Structures : The study has shown that rain water harvesting structures have been installed only in less than two-fifth (36%) of the sample GPs. Surprisingly, none of the GPs in West Bengal and Assam have reported about installing such structures.

14. Recommendations

14.1 Recommendations

In order to achieve the objectives and goals of any development scheme, it is essential that its strengths are sustained and consolidated, and that the shortcomings are minimized by way of appropriate and timely corrective actions and applying the lessons learned. The recommendations derived from the study findings are to be viewed in this context.

1. The focus of the Rajiv Gandhi National Drinking Water Mission (RGNDWM) was to adopt a community-based demand-driven approach instead of the hitherto government forced supply driven approach. The demand-responsive approach is based on the principles of community participation and decentralization of powers for implementing and operating drinking water supply schemes with the government playing the role of a facilitator. Demand-driven programs are found to have relatively low institutional cost and other advantages, including better O&M cost recovery. *In the light of the fact that in most cases, the Village Water and Sanitation Committees (VWSCs) are non-functional, the first step would therefore be to revitalize these committees and build the capacity of their members. Only then, the goals and objectives of the Mission can be realized.*
2. Sustainability of water supply systems can be ensured only by ensuring the sustainability of the water sources through efficient water resource management initiatives. For the purpose, the need for active community involvement at every stage – from planning, to implementation, operation and maintenance (O&M) and ownership can hardly be overemphasized. *In the light of the study revealing a near total absence of community involvement (what to talk of the involvement of women), it becomes crucial to engage specialist agencies for capacity building of VWSC members. Only then, the needs and aspirations of the rural poor can be fulfilled.*
3. The study has revealed that close to nine-tenth (87%) households have denied about any awareness campaign organized in their villages. In the near absence of IEC activities, it is no surprise that open defecation is so widely prevalent in most (80%) of the sample habitations. Besides, there is no functional mechanism for garbage collection, as reported by almost all the sample habitation (96%). *In this backdrop, it would be worthwhile to take-up focused and sustained IEC campaigns to educate the communities on the various aspects and issues related to drinking water, sanitation and hygiene. This would also motivate the communities, especially the women for their active involvement in all aspects of the Mission, including its operation & maintenance. For the purpose,*

experienced professional agencies may be hired to develop appropriate and effective IEC tools.

4. The study has revealed that over half of the Gram Panchayats have expressed that they are not capable to take the responsibility of O&M. Besides, in a large majority of the Gram Panchayats (50 out of 63), O&M of the assets created under the Mission have not been formally handed over to them. It may be highlighted that 71% of the sample GPs have even denied about the provision of field testing kits for water quality monitoring. As such, the communities as well as the elected representatives are generally not enthusiastic or self-motivated to participate in the decentralized planning process, largely due to lack of proper understanding of the nature and scope of the schemes. *In this scenario, there is an urgent need to organize relevant training programs for the village level PRI members so as to motivate them for their active involvement in all aspects of the Mission. For the purpose, professional training agencies may be hired.*
5. In many instances, a majority of the households across all the 5 study states have complained about the ill-maintained water supply system resulting in frequent breakdowns and consequently, adversely affecting the desired quantity or quality of drinking water available to them. *The program managers may consider a separate and adequate budgetary provision, besides deputing a team of dedicated staff for ensuring timely repairs and preventive maintenance of the assets created under the project.*
6. Installation of rain-water harvesting is one of the key components of the RGNDWM. However, the study has shown that rain water harvesting structures have been installed only in less than two-fifth (36%) of the sample GPs. Surprisingly, none of the GPs in West Bengal and Assam have reported about installing such structures. *In view of this, there is an urgent need for the renewed impetus in taking-up this important water conservation measure in a serious manner.*
7. Study has revealed about the instances where the water supply provisioning under the Mission was inappropriate. For example, in many parts of Rajasthan and Karnataka where water table is very deep, generally the hand pump schemes have not been successful. *In order to ensure effectiveness and long-term sustainability of the rural water supply schemes under the Mission, it is imperative to design State-specific plans of action keeping in mind the needs and aspirations of the rural populations.*
